INDEX

NAME INDEX

CROMBIE, Prof. Patrick (Forshaw, J. H., and) : County of London lan, *review*, 227
J. S. : *Death* of, 744
: Resolution of the Carbon Dioxide Bands at $2{\cdot}01\mu$ and $2{\cdot}05\mu$ in he Solar Spectrum, 361
Prof. Edward F. : Physiological Regulations, *review* by Dr. O. A. owell, 735
tising Service Guild : An Enquiry into People's Homes (Report epared by Mass-Observation), *review* by Lieut. T. H. Hawkins, 257
ical Society, Royal : Collection of aeronautical medals, 532
(South) Institute for Medical Research : Annual Report for 1942, 6
al Bureaux, Imperial : The Production of Seed of Root Crops and getables, 410
ort on the, 731
ural Education Association : Summer Conference, 165
th, Dr. G. C., and Bisby, Dr. G. R. : A Dictionary of the Fungi, *review*, 614
onomy and Distribution of the Fungi, 633
istry : Sir George Thomson appointed scientific adviser, 596
er, Dr. A. E. : Practical Emulsions (H. Bennett), *review*, 371
vén, Dr .H. : Non-Solar Planets and the Origin of the Solar System, 721
, Prof. W. E. : Where Angels Fear to Tread, a Contribution from General Sociology to Human Ethics, 309
rof. Charles M. : Awarded an Elliot Cresson Medal of the Franklin stitute, 45
. H. S. : James Prescott Joule and the Unit of Energy, 354
. D. : D.Sc.(Econ.) of the University of London conferred on, 534
A. S. (Steel, R. W., and) : Protective Systems for Rural Electrical stribution, 26
orge : Photographic Survey of Galactic Clusters, 220
Amaryllis Society : *Herbertia* for 1942, 481
Philosophical Society : Celebration of the bicentenary of the n of Thomas Jefferson, 657
. C., and Parkes, Dr. A. S. : X-Irradiation of Rabbit Spermatozoa *itro*, 244
. W. : Gem Testing for Jewellers, *review*, 6
Dr. D. S. : Future of Technical Colleges, 388
F. B. : A New Tuned Null Detector, 361
Sir John : Post-War Needs of Universities in Great Britain, 595
J. G. C. : The Highland Border Series in Bute, 277
J. S. (Clark, Merial C., and) : Semi-conducting Properties of nous Sulphide, 75
rof. E. N. da C. : Vibrations and Waves, 502
d Twinning in Single Crystals of Mercury, 567
a, H. E. : Diapause in the Eggs of a Grasshopper, 107
E. : Clinical Photography, 423
, J. P. (Barrer, R. M., and) : Future of Technical Colleges, 80, 1, 387
Czechoslovak Founders Committee : Prizes for essays on an Inter-Allied Charter of Health, 534
, Sir A. Stanley : Elected president of the Institution of Electrical Engineers for the Year 1943–44, 74
Telecommunication, 501
rooy, A. van : Science Under Fascism and Democracy, 306
thropological Institute, Royal : Centenary Meeting, 444, 587
Huxley Memorial lecture by Prof. F. C. Bartlett, 596, 710
pleton, Sir Edward : Opening of the new physico-chemical laboratories of the British Coal Utilization Research Association, 16, 324
Honorary degree of doctor of laws of the University of Birmingham conferred on, 44
s at the Preliminary Meeting of the Standing Consultative ference on Fuel Research, 532
. Muriel A. : *Obituary* of Prof. Charles Schuchert, 15
Prof. Raymond C. : Retirement from Brown University, 211
, Dr. R. E. G. : The Pattern of Youth, an Interim Report, 217
ey of Canadian Schoolchildren, 391
tal Survey of the British Isles, 630
y of Dr. George Washington Carver, 685
. Dr. E. F. : Elected president of the Royal Society of Arts, 43
ces in Biochemistry, *review*, 612
ne Long Road of Progress, 687
Royal Society of : Dr. E. F. Armstrong elected president, 43
under the Thomas Gray Memorial Trust, 101
an Wood Lecture on Science in Soviet Russia (J. G. Crowther), 138
A Programme for the, 687
Ashby, Prof. A. W. : Milk, 238
her, Prof. Leon : *Death* of, 531
worth, Dr. J. R. : Variations of Ultra-Violet and Daylight Rays, 330
3 : Training Course in Special Librarianship, 45
Report of the Proceedings of the Seventeenth Conference, 100
War-Time Guides to British Sources of Specialised Information, No. 5, Engineering other than Electrical, 186
Conference on the Rehabilitation of Special Library and Information Services, 298
Annual Conference, 480
Asquith, Sir Cyril : Appointed chairman of a Colonial Office Commission to inquire into Higher Education in the Colonies, 211
Astbury, Dr. W. T. : Textile Fibres under the X-Rays, *review* by F. Ian G. Rawlins, 90
Astronomer Royal : Annual Report of the, 700
Astronomical Association, British, and the Royal Astronomical Society : Popular lectures on Astronomy, 720
Astronomical Society, Royal : Old letters received by Nathaniel Pigott presented to the, 623
Astronomical Society, Royal, and the British Astronomical Association : Popular lectures on Astronomy, 720
Athens, British School at : The Annual of the, No. 40, Session 1939–40, *review* by Prof. R. M. Dawkins, 229
Atkinson, H. B. : Appointed inspector of plants and produce, Gold Coast, 473
Atwood, Alice C. (Blake, S. F., and) : Geographical Guide to the Floras of the World, Part I : Africa, Australasia, Insular Floras, North America and South America, *review* by Dr. W. A. Sledge, 202
Avineri-Shapiro, Mrs. S. (Hestrin, Shlomo, and) : Mechanism of Polysaccharide Production from Sucrose, 49
Awbery, J. H. : James Prescott Joule and the Unit of Energy, 479

BABKIN, Prof. B. P. : Awarded the Flavelle Medal of the Royal Society of Canada, 362
Secretory Mechanism of the Digestive Glands, 363
Bacharach, A. L. : Milk, 238
Back, A. (Halberstaedter, L., and) : Influence of Colchicine Alone and Combined with X-Rays on Paramecium, 275
Bacon, Prof. F. : *Death* of, 269 ; *Obituary*, 350
Baden-Powell, D. F. W. : High-Angle Edge Flaking of Flint, 663
Bägman, G. (Bonnier, G., Nordenskiöld, M., and) : Bar-eye Locus in *Drosophila melanogaster*, 219
Bailey, Dr. E. B. : *Obituary* of Baron Gerard de Geer, 209
Awarded a Royal Medal of the Royal Society, 559, 666
Geology in the War and After, 728
Bainbridge, John : Tercentenary of, 532
Bainbridge-Bell, L. : Time Base Circuits, *review*, 116
Baker, Prof. H. F. : *Obituary* of Dr. G. T. Bennett, 558
Baker, H. G. : Petal-Colour Inheritance in Lychnis, 161
Baker, Dr. John R. : Colour of Red Blood Corpuscles, 331
Baker, Dr. J. W. : An Introduction to Organic Chemistry, *review*, 90
Baker, Prof. M. B. : Gold and Iron Prospects in Canada, 362
Baker, R. E. D., and Crowdy, S. H. : Witches' Broom Disease of Cacao, 361
Baker, W., Grice, K. D., and Jansen, A. B. A. : Synthesis of some α-Acyltetronic Acids, 108
Ballen, Dr. Don Francisco : Awarded a Howard A. Potts Medal of the Franklin Institute, 45
Balls, Dr. W. Lawrence : Precision Hygrometry with a Wet-Bulb, 389
Balogh, T. : The Foreign Balance and Full Employment, 560
Balson, E. W., and others : Importation of Technical Literature into Great Britain, 479
Bamford, Mrs. : Problems of Freed Europe, 634
Banerjee, Sachchidananda : Vitamin C and Carbohydrate Metabolism, 329
Banerji, Prof. A. C. : Recent Advances in Galactic Dynamics, *review*, 492
Bangham, Dr. D. H. : *Obituary* of Prof. Isidor Traube, 743
Bankier, Dr. Enid : Appointed demonstrator in zoology to medical and dental students in the University of Sheffield, 473
Barbier and Chalonge : Stellar Continuous Spectra, 697
Barcroft, Sir Joseph : Awarded a Copley Medal of the Royal Society, 559, 665
The Tetrapyrrolic Pigments, 716
Barker, Dr. L. F. : *Obituary* by Dr. J. D. Rolleston, 407
Barker, T. Sankey (Went, Arthur E. J., and) : Salmon and Sea Trout of the Waterville (Currane) River, 332
Barkworth, Capt. H. : Milk, 238
Barlow, Dr. Guy : To retire from the lectureship in physics in the University of Birmingham, 46
Barlow, H. B. (Rushton, W. A. H., and) : Single-Fibre Response from an Intact Animal, 597
Barnard, Cyril C. : Library Stocks of Periodicals, 106, 243
Barnes, Alfred S. : High-Angle Edge Flaking of Flint, 477
Barnes, Dr. B. : Lower Aquatic Fungi, *review*, 462
Barrer, R. M., and Andrews, J. P. : Future of Technical Colleges, 80, 131, 387
Barron, Dr. N. S. : Milk, 238
Barry, Prof. Frederick : *Death* of, 351
Barry, Dr. Vincent C. : Regulated Degradation of 1, 3 Polysaccharides, 537
Bartlett, Prof. F. C. : Anthropology in Reconstruction (Huxley Memorial lecture of the Royal Anthropological Institute), 596, 710
Barton-Wright, Dr. E. C., and Booth, R. Gordon : Microbiological Assay of Riboflavin, 414
Barton-Wright, Dr. E. C., Moran, Dr. T., and Sarson, H. S. : Riboflavin and Vitamin B_1 in Nineteenth Century Buns and Ale, 273
Bateman, L., and Jeffrey, Dr. G. A. : Structure of Geranylamine Hydrochloride, 446
Bates, Dr. G. H. : Propagation of Potato Seed Tubers from Stems, 135
Bauer, Prof. Walter (Bennett, Prof. Granville A., Waine, Dr. Hans, and) : Changes in the Knee Joint at Various Ages, *review*, 35
Baynes, Dr. H. G. : *Death* of, 323 ; *Obituary* by John Layard, 406
B.B.C. : Talks on Science at your Service, 325
Coming-of-Age of the, 622
Beadnell, Surgeon Rear-Admiral C. M. : An Encyclopædic Dictionary of Science and War, *review* by Dr. L. E. C. Hughes, 119
Beaumont, F. N., and Geary, F. A. : Maintenance of Distribution Plant and Mains on A. C. Networks, 747

Beck, Dr. Stephan : Aqueous Soap Solutions of Carcinogenic Hydrocarbons, 537
Beckinsale, R. P. : Land, Air and Ocean, *review*, 399
Beevers, Dr. C. A. : Change of Symmetry of Basic Beryllium Acetate, 447
Beevers, Dr. C. A. (Macewan, Dr. D., and) : Numerical Fourier Analysis to Twenty-Nine Harmonics, 303
Begbie, G. H., and Born, Prof. Max : Thermal Scattering of X-Rays by Crystals, 19
Begg, Michael, and Hogben, Prof. Lancelot : Localization of Chemoreceptivity in Drosophila, 535 ; *erratum*, 562
Bell, Julia : On Pseudohypertrophic and Allied Types of Progressive Muscular Dystrophy, *review* by Dr. F. W. Sansome, 260
Bell Laboratories : A new specialty Rubber, 'Paracon', 297
Giant Camera Installed in the Photocopy Department (Richard Haard), 335
Bellerby, J. R. : Economic Reconstruction, Vol. I, *review* by G. D. H. Cole, 312
Benes, Dr. : Honorary degree of doctor of laws of the University of Birmingham conferred on, 44
Bengough, Dr. G. D. : Research and Ships' Antifouling Paints, 159
Bennett, Prof. Granville A., Waine, Dr. Hans, and Bauer, Prof. Walter : Changes in the Knee Joint at Various Ages, *review*, 35
Bennett, Dr. G. T. : *Death* of, 442 ; *Obituary* by Prof. H. F. Baker, 558
Bennett, H. : Practical Emulsions, *review* by Dr. A. E. Alexander, 371
Benson, R. B. : Studies in Siricidæ or Wood-wasps, 24
Benstead, J. : Appointed a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, 444
Bequaert, J. : Pleistocene Molluscs of Burma, 335
Bergel, Dr. F., and others : An Antibacterial Substance from *Aspergillus clavatus* and *Penicillium claviforme* and its Probable Identity with Patulin, 750
Berkeley, Dr. C. : Science, Christianity and Truth, 479
Bernal, Prof. J. D. : Science and the War Effort, 422
Bertram, C. K. Ricardo : Production of Freshwater Fish in Palestine, 415
Best, Surgeon Commander C. H. : Medical Investigations as Applicable to the Armed Forces, 362
Besterman, Theodore : International Rehabilitation of Special Library Services, 480
Bevan, Prof. A. D. : *Death* of, 351
Bevan, Dr. Edwyn : *Death* of, 471
Bevan, Dr. William Llewellyn Pryce : Bequest of £22,000 to the University of Edinburgh, 658
Bhatnagar, Lt.-Col. S. S. : A Precipitin Test for Typhoid Fever, 448
Bibby, Cyril : Plain Words, a Guide to Sex Education (W. J. Thomas), *review*, 35
Simple Experiments in Biology, *review*, 614
Biffen, Sir Rowland : *Obituary* of Sir Thomas Middleton, 97
Biggs, Dr. B. S. (Fuller, Dr. C. S., and) : Synthesis of 'Paracon', 297
Billington, E. M., McCance, Dr. R. A., and Widdowson, E. M. : War-time Growth of Schoolboys, 187
Biochemical Society : Discussion on the Tetrapyrrolic Pigments, 534, 714
Bird Preservation, International Committee for : Joint meeting of the British and Polish Sections, 409
Birkbeck College : Prof. H. Gordon Jackson appointed Master, 531
Birkeland, Prof. Jorgen : Microbiology and Man, *review* by Dr. R. St. John-Brooks, 674
Birkinshaw, Dr. J. H. : Patulin, 620
Birmingham, Lord Mayor of : Science under Fascism and Democracy, 306
Bisby, Dr. G. R. (Ainsworth, Dr. G. C., and) : A Dictionary of the Fungi, *review*, 614
Taxonomy and Distribution of the Fungi, 633
Bishara, S. (Fathy, A.), and Hassanein, S. A. M. : Flow of Viscous Fluids, 512
Blackwelder, Richard E. : Staphylinidæ of the West Indies, 219
Blainey, Alan : Four Years of Planned Feeding in Great Britain, 191
Blair, A. A. : Obstructions in Newfoundland and Labrador Rivers, 753
Blair, Dr. G. W. Scott : *Obituary* of Dr. E. C. V. Mattick, 183
A New Criterion for Expressing the 'Intensity of Firmness' of Soft Bodies, 412
Blair, Dr. G. W. Scott (Schofield, Dr. R. K., and) : Bulb Correction in Capillary Tube Viscometry, 477
Blake, S. F., and Atwood, Alice C. : Geographical Guide to the Floras of the World, Part I : Africa, Australasia, Insular Floras, North America and South America, *review* by Dr. W. A. Sledge, 202
Blaxter, K. L. : Stimulation of the Milk Production of Dairy Cows by Feeding Thyroid-active Iodinated Proteins, 751
Blewett, M. (Fraenkel, Dr. G., and) : Intracellular Symbionts of Insects as a Source of Vitamins, 506
Bloch, O. : *Obituary* of F. F. Renwick, 379
Boalt, Carin, and Zotterman, Yngve : Rations and Food Consumption in Sweden during 1942–43, 635
Bohr, Prof. Niels : Escape from Denmark, 596
Bond, T. E. T. : Henry Trimen, F.R.S. (1843–96), 470
Bonnier, G., Nordenskiöld, M., and Bägman, G. : Bar-eye Locus in *Drosophila melanogaster*, 219
Boorman, Miss Kathleen E., and others : Recognition of *Rh* Genotypes in Man, 563
Boot, Sir Horace : Bequests of, 382
Booth, R. Gordon (Barton-Wright, Dr. E. C., and) : Microbiological Assay of Riboflavin, 414
Boothroyd, E. R. (Smith, S. G., and) : Interlocking of Bivalents in *Trillium erectum*, 219
Born, Prof. Max (Begbie, G. H., and) : Thermal Scattering of X-Rays by Crystals, 19
Borucki, Dr. Jul : Bird Preservation, 409
Bose, B. C., and Mukerji, Dr. B. : Physiologically Active Fractions of Indian Hemp, 109
Bose, S. R. : Binucleate Oidia on Binucleate Mycelium of *Polystictus hirsutus* Fr., 508
Bossard, Prof. J. H. S. : Sociological Value of Family Meals, 271
Bourne, Dr. Geoffrey : War-Time Food for Mother and Child, *review*, 371
Scientific and Medical Aspects of Post-War Nutritional Relief, 616
Problems of Freed Europe, 63[illegible]
Vitamin P Deficiency in Guinea-pigs, 659
Bousfield, W. R. : *Death* of, 156
Bovey, Dr. : Protective Finishes for Scientific Apparatus, 272
Bowen, E. J. : Colour of Red Blood Corpuscles, 476
Bowen, Prof. Norman Levi : Awarded the Willet G. Miller Medal of the Royal Society of Canada, 362
Bowles, Dr. P. Ewart : Research and Ships' Antifouling Paints, 159
Bowley, Prof. A. L. : Honorary degree of D.Litt. of the University of Oxford conferred on, 131
Boyd, Prof. William C. (Schiff, Dr. Fritz, and) : Blood Grouping Technic, *review* by Dr. John F. Loutit, 520
Brabazon, Lord : Scientific Research in Great Britain, 129
Bracken, A. : Patulin, 620
Bradfield, Dr. J. J. C. : *Death* of, 408
Bradford, Dr. S. C. : The Co-ordination of Abstracting, 481
Bradley, Dr. O. Charnock : Topographical Anatomy of the Dog, revised by Prof. Tom Grahame, fourth edition, *review*, 648
Bragg, Sir Lawrence : The History of X-Ray Analysis, *review* by F. Ian G. Rawlins, 463
The Physical Optics of X-Ray Analysis, 542
Brahmachari, Sir U. N. : Presidential address to the Indian Association for the Advancement of Science, 622
Braid, Prof. K. W., and Conway, Elsie : Rate of Growth of Bracken, 750
Braidwood, R. J. : Archæological Work in Iraq, Palestine, Kenya, Morocco, England, etc., 473
Braude, R. : Value of Horse Chestnuts as Food for Pigs, 571
Brenchley, Dr. Winifred E. : Weed Control, *review*, 314
Brett, Prof. G. S. : Effect of the Discovery of the Barometer on Contemporary Thought, 719
Bridgman, Prof. P. W. : Science and its Changing Social Environment, 85
Briggs, G. W. G. : Appointed senior agricultural officer, Nigeria, 624
Briggs, P. Stanley : Rheology in the Textile, Leather, Shoe and Allied Trades, 514
Brightman, R. : *Obituary* of Sir James Morton, 440
Brimble, L. J. F., and May, Frederick J. : Social Studies and World Citizenship, *review* by J. A. Lauwerys, 339
Briscoe, H. V. A., and co-workers : Hydrogen Exchange Reactions, 757
British Association : Conclusions of the Committee on Scientific Research on Human Institutions, 669
British Association of Refrigeration : To change its title to the Institute of Refrigeration, 473
British Broadcasting Corporation : Talks on Science at your Service, 325
Coming-of-Age of the, 622
British Coal Utilization Research Association : Opening of new physico-chemical laboratories by Sir Edward Appleton, 16, 324
Conference on the Utilisation of Small Coals, 213
British Commonwealth Science Committee : Report on Co-operation in Scientific Research, 29
British Council : Report for the Year ending March 31, 1943, 270
British Drug Houses, Ltd. : Retirement of Charles Alexander Hill as chairman and managing director, 442
Appointment of Dr. F. H. Carr as chairman, and F. C. Oscar Shaw as managing director, 442
Work of Dr. F. H. Carr, 471
British Ecological Society : Discussion on Ecological Principles in Forestry Practice, 196
British Plastics Federation : Dr. W. E. le B. Diamond appointed general manager, 46
British School at Athens : The Annual of the, No. 40, Session 1939–40, *review* by Prof. R. M. Dawkins, 229
British Trust for Ornithology : Sixth Bulletin on Wood Pigeon Studies, 533
British X-Ray and Radium Protection Committee : Report on Protection from X-Rays and Radium, 73
Brodetsky, Prof. S. : Education After the War, 222
Brodskaja, E. (Nikonov, V., and) : Photo-electric Colorimetry of *B8–B9* Stars, 746
Bromehead, C. E. N. : Elected president of the South-Eastern Union of Scientific Societies for 1943–44, 224
Geology and Health, 224
Bronk, Lester B. (Liebhafsky, Herman A., and) : Surface 'Memory' in a Carboy, 695
Broom, Dr. R. : An Ankle-Bone of the Ape-Man, *Paranthropus robustus*, 689
Brown, A. G. (Crane, M. B., and) : Pollination of Plums, 24
Brown, A. G. (Crane, M. B.,) and Lewis, D. : Seedless Fruits of Fertility and Conference Pears, 24
Brown, G. S. : Appointed a senior agricultural assistant, Tanganyika Territory, 18
Brown, Prof. H. P., and Panshin, Prof. A. J. : Commercial Timbers of the United States, *review* by Alexander L. Howard, 259
Brown, K. I. : Protective Systems for Rural Electrical Distribution, 26
Brown University : Retirement of Prof. Raymond C. Archibald, 211
Browne, Major G. St. J. Orde : Labour Conditions in Ceylon, Mauritius and Malaya, 203
Brownlee, L. D. : X-Rays in the Study of Sintered Carbides used for Tool-tips, 543
Brumberg, E. M. : Colour Microscopy in Ultra-Violet Rays, 357
Brunt, Prof. D. : Meteorology as a Cultural Subject, *review*, 585
Brunton, Sir Stopford Lauder : *Death* of, 183 ; *Obituary*, 269
Bryan, Dr. W. R., and Shimkin, Dr. M. B. : Relative Potency of Carcinogenic Hydrocarbons, 360
Bull, Anders Henrik : Awarded the Louis Edward Levy Medal for 1943 of the Franklin Institute, 45
Bumpus, Dr. H. C. : *Death* of, 241
Bunbury, Sir Henry (Young, M., and) : Will the War Make Us Poorer ?, 157
Bunge, Prof. A. E. : *Death* of, 408
Bunge, Mario : El Tricentenario de Newton, 719
Bunn, C. W. : Cinematograph Films of Growing Crystals, 543
Bunting, Dr. : Problems of Freed Europe, 634
Burch, Dr. C. R. : A Technologist Looks at the Future, 523
Reflecting Microscopes, 748
Burgess, R. C. : Appointed director of surveys and lands, Sierra Leone, 213
de Burgh, Prof. W. G. : *Death* of, 269
Burk, R. E., and Grummitt, Oliver, edited by : The Chemical Background for Engine Research, *review* by Prof. D. M. Newitt, 675
Burke, Frederick, and Williams, E. G. : Newt Larvæ in Brackish Water, 566
Burkitt, M. C. : Place-Names of Cambridgeshire, *review*, 145
Early Britain, *review*, 174
The Mumbwa Caves, Northern Rhodesia, 252
Research on Early Man in Burma, 335
Burns, W. : Degree of D.Sc. of the University of Aberdeen conferred on, 46

rt, Prof. Cyril : Factorial Analysis of Physical Growth, 75
ton, Prof. E., F. : Electron Microscope Studies of the Capture of Airborne Particles by Single Fibres, 540 ; *erratum*, 596
y, Henry : High-Angle Edge Flaking of Flint, 664
cher, A. Dunbavin : Observations on Some Phases of the Life Cycle of *Ichthyophthirius multifiliis* Fouquet 1876, 753
ler, F. H. C. : Appointed honorary secretary of the Council for the Promotion of Field Studies, 717
ng, E. S. : Post-Entry Training for Administration from the Industrial Aspect, 99

CADMAN, C. H. : Nature of Tetraploidy in Cultivated European Potatoes, 103
ajal, Ramon y : Dedication of a histological laboratory to the memory of (Spanish Cultural Institute at Buenos Aires), 596
allan, Dr. E. McC. : Sex Ratio affected by Host Plant, 162
Thrips Resistance in Cacao, 332
llan, H. G. : Distribution of Nucleic Acid in the Cell, 503
lma, Italo, and Foster, Charles L. : Trypan Blue and Cell Migration in the Adrenal Cortex of Rats, 536
on, W. E. : Appointed assistant Government analyst, Tanganyika Territory, 18
ampbell, Dr. I. G. M., and others : Importation of Technical Literature into Great Britain, 479
Campbell, Dr. Norman R. : Science, Christianity and Truth, 192
Campbell, T. G. (Wilson, F., and) : St. John's Wort in Australia, 746
Canada, Dominion Government of : Plants and equipment for the production of penicillin, 502
Carnegie Institution of Washington : Year Book No. 41, 139
Carnegie United Kingdom Trust : Twenty-ninth Annual Report, 242
Carr, Dr. F. H. : Appointment as chairman of the British Drug Houses, Ltd., 442 ; Work of, 471
Carrasco, R. (Lorón, M. Martin), and Gullón, E. : Observations of Solar Prominences and Sunspots in 1937, 25
Carter, E. J. : International Rehabilitation of Special Library Services, 480
Carver, Dr. George Washington : *Obituary* by Dr. R. E. G. Armattoe, 685
Case, Robert A. M. : Siderocytes in Mammalian Blood, 599
Casey, R. G. : Honorary degree of doctor of laws of the University of Birmingham conferred on, 44
Cashmore, A. B. (Moore, R. M., and) : St. John's Wort in Australia, 746

United States National Academy of Sciences : Charles L. Mayer Award for 1943, 720
United States National Research Council : Handbook of Scientific and Technical Societies and Institutions of the United States and Canada, fourth edition 562
Universities' Federation for Animal Welfare : Circular on the Conservation of Wild Life in Great Britain, 443
University of Aberdeen : Conferment of degrees, 46
University of Birmingham : Conferment of the honorary degree of doctor of laws on Dr. Benes, J. G. Winant, R. G. Casey, Sir Edward Appleton and Dr. H. R. Ricardo, 44
  Dr. P. B. Moon given the title of reader in atomic physics, 46
  Dr. R. R. Nimmo appointed lecturer in physics, 46 ; *erratum*, 158
University of Cambridge : Summer School in X-Ray Crystallography, 46
  Prof. R. A. Fisher appointed to the chair of genetics, 156
  Lieut.-Colonel W. B. R. King appointed Woodwardian professor of geology, 531
  Retirement of Prof. O. T. Jones from the Woodwardian professorship of geology, 559
University of Durham : Appointment of Dr. L. R. Wager to the chair of geology, 686
University of Edinburgh : Bequest by Dr. William Llewellyn Pryce Bevan of £22,000 for the promotion of the teaching or the advancement of medical science, 658
  Prof. Maria Gutowska and Dr. A. Jablonski added to the teaching staff of the Polish School of Medicine, 658
University of Leeds : Honorary degree of LL.D. conferred on Prof. H. S. Raper, 131
  Honorary degree of D.Sc. conferred on E. V. Evans, 131
University of Liverpool : Retirement of Prof. H. J. Channon from the Johnston chair of biochemistry, 71
University of London : Title of professor emeritus of the history of medicine conferred on Dr. Charles Singer, 46
  Conferment of degrees of D.Sc., 46, 534
  Harold Claughton appointed principal, 156
  Roosevelt, 272
  Degree of doctor of laws *honoris causa* conferred on President
  Lectures and discussions on Engineering Economics (Sir Frank Gill), 272
  Title of professor of technical optics conferred on Dr. L. C. Martin, 720
University of London Institute of Archæology : Conference on the Future of Archæology, 320
University of London Institute of Education : Foundation for Educational Research, 717
University of Michigan : A Direct-Intensity Microphotometer, 753
University of Oslo : Message of sympathy from the Conference of Ministers of Education of the Allied Governments, 717
University of Oxford : Honorary degree of D.Litt. conferred on Prof. A. L. Bowley, 131
  History of the (Prof. F. M. Powicke), 221
  Research Department in Ophthalmology, 323
  Acceptance of an offer of £8,000 a year from the Lord Nuffield Provincial Hospitals Trust for research in plastic surgery, 720
University of Peiping : Fortieth Anniversary of the (Prof. Ch'ang Ch'ing-Yueh, Dr. Joseph Needham, and Prof. Sun Yün-Chu), 23
University of Sheffield : Appointments, 473
  George Hurst appointed lecturer in mining and mine surveying, 596
  Renewal of the Rockefeller Foundation grant for research in biochemistry, 596
University of Toronto : Meetings to commemorate the invention of the Barometer, 718
University of Valencia : Observations of Solar Prominencies and Sunspots in 1937, 25
University College, Dublin : Resignation of Prof. R. A. S. Macalister from the chair of Celtic archæology, 272
  Appointment of Prof. S. F. O'Riordan to the chair of Celtic archæology, 272
University Grants Committee : Increase in membership, 717
University Professors and Lecturers of the Allied Countries in Great Britain, Association of : Conference on Education After the War, 221
  Prof. Jean Timmermans elected president, 222
Urey, Prof. Harold C. : Awarded a Franklin Medal of the Franklin Institute, 45
U.S.S.R. Academy of Sciences : Activity of the, 324
  Election of new academicians and corresponding members, 500

Wisdom, John : Other Minds (7), 623
Wishart, Dr. John : Statistical Tables for Biological, Agricultural and Medical Research (Prof. Ronald A. Fisher and Dr. Frank Yates), second edition, *review*, 491
Wishart, Dr. John (edited by Pearson, E. S., and) : "Student's" Collected Papers, *review* by Dr. K. Mather, 551
Wishart, J. M., Jepson, C., and Klein, L. : Vacuum Filtration of Sewage Sludge, 249
Witherby, H. F. : *Death* of, 744
Witts, Prof. L. J. : Appointed a member of the Medical Research Council, 658
Wokes, Dr. Frank : Ultra-Violet Light and Apparent Vitamin C, 328
Wokes, Dr. Frank (Melville, Ronald), and Organ, Joan G. : Apparent Vitamin C in Walnuts, 447
Wokes, Dr. Frank, and others : Apparent Vitamin C in Certain Foodstuffs, 14
Woledge, G. : Functions of the Special and General Libraries, 687
Wolters, A. W. : Dynamics in Psychology, *review*, 172
Wood, Dr. W. A. : X-Rays in Industry, *review*, 145
Wood Jones, Prof. F. : The Bushman Tribes of Southern Africa (A. M. Duggan-Cronin), *review*, 147
  John Gilbert, Ornithologist, *review*, 286
Woodhouse, Dr. D. L. (Donovan, H., and) : A Speculation on the Nature of the Chemical Structure which is the Essence of the Malignant Cell, 509
Woodruff, L. L. : Longevity of Paramecium, 419
Woods, H. : *Obituary* of Dr. T. T. Groom, 183
Wooldridge, Dr. : Milk, 238
Woolley, Sir Leonard : The Future of Archæology, 321
Woolton, Lord : Appointed Minister of Reconstruction, 594
Worden, Alastair N. : Xanthine Oxidase Activity of Cow's Milk, 505
Wornum, —. : Protective Finishes for Scientific Apparatus, 272
Worthington, Dr. E. B. : To accompany Dr. B. A. Keen as scientific adviser to the Middle East Supply Centre, Cairo, 473
Wright, Sir Almroth E. : Studies on Immunisation, First Series, *review*, 614
Wulff, E. V. : An Introduction to Historical Plant Geography, authorized translation by Elizabeth Brissenden, *review* by Dr. H. Godwin, 490
Wylie, Thomas S. : Science Class Lecture Cine-Films, 623

X-RAY and Radium Protection Committee, British : Report on Protection from X-Rays and Radium, 73

YAP, P. M. : Science under Fascism and Democracy, 306
Yarwood, T. M. : School Physics, Part 1, *review*, 260
Yates, Dr. Frank (Fisher, Prof. Ronald A., and) : Statistical Tables for Biological, Agricultural and Medical Research, second edition, *review* by Dr. J. Wishart, 491
Yates, Dr. P. Lamartine : Scientific and Medical Aspects of Post-War Nutritional Relief, 616
Yates, Dr. P. Lamartine, and Warriner, D. : Food and Farming in Post-War Europe, *review*, 399
Yeld, J. D. : Appointed agricultural officer, Northern Rhodesia, 353
Yonge, Prof. C. M. : Marine Biology in the West Indies, 136
Young, Prof. James : *Death* of, 686
Young, M., and Bunbury, Sir Henry : Will the War Make Us Poorer ?, 157
Youth Advisory Council : Report on the Youth Service after the War (Board of Education), 455
Yün-Chu, Prof. Sun (Ch'ing-Yueh, Prof. Ch'ang, Needham, Dr. Joseph, and) : Fortieth Anniversary of the University of Peiping, 23

ZECHMEISTER, Prof. L., and Cholnoky, Dr. L. : Principles and Practice of Chromatography (translated from the second and enlarged German edition by A. L. Bacharach and F. A. Robinson), second impression, *review*, 35
Zeeman, Prof. Pieter : *Death* of, 471
Zepler, Dr. E. E. : The Technique of Radio Design, *review*, 399
Zeuner, Dr. F. E. : Training for Archæologists, 321
Zinn, Donald J. (Pennak, Robert W., and) : Mystacocarida, a New Order of Crustacea from Intertidal Beaches in Massachusetts and Connecticut, 167
Zoological Society of London : Course of popular lectures on Natural History, 101
  Prof. Edward Hindle appointed scientific director, 353, 380
Zotterman, Yngve (Boalt, Carin, and) : Rations and Food Consumption in Sweden during 1942–43, 635

SUBJECT INDEX

ABSENTEEISM among Women (Industrial Health Research Board Emergency Report No. 4.), 622
Absorption and Ghost Formation : Tablet (Dr. S. J. Folley), 134
Absorption Bands of Water Vapour : Hitherto Unidentified (Dr. T. G. Cowling), 694
Absorption Spectra in Medicine, *review* by Dr. R. A. Morton, 342
Abstract Services : Overlapping (James S. Ridsdale), 217
Abstracting : The Co-ordination of, 481
A.C. Networks : Maintenance of Distribution Plant and Mains on (F. N. Beaumont and F. A. Geary), 747
Acetylcholine and Vitamin B_1 in Nervous Excitation : Role of (Prof. A. v. Muralt), 188
Acid Neutralization in Insulating Papers (D. A. McLean), 140
Acids (Nucleic) : Terminology of (Dr. A. W. Pollister and Dr. A. E. Mirsky), 692
Acids in Animal Tissues : Ribonucleic (Dr. J. N. Davidson and Miss C. Waymouth), 47
Acoma Pueblo Indians : Origin Myth of the (M. W. Stirling), 24
Acoustic Centre of the Frog (Primary) : Electrical Responses from the (J. Ek and C. L. v. Euler), 132
Acyl Migration in Steroids (V. A. Petrow, O. Rosenheim and W. W. Starling), 25
α-Acyltetronic Acids : Synthesis of some (Wilson Baker, K. D. Grice and A. B. A. Jansen), 108
Adipose Tissue after Insulin Injection : Glycogen in (Prof. E. Wertheimer), 565
Administration from the Industrial Aspect : Post-Entry Training for (E. S. Byng), 99
Administrative Staff College : A National, 100, 472
Adolescence and some Problems of Youth Training (Prof. C. W. Valentine), 122
Adrenal Cortex of Rats : Trypan Blue and Cell Migration in the (Italo Calma and Charles L. Foster), 536
Adult Education in H. M. Forces (Major J. O. R. Phillips and Dr. S. J. Curtis), 166
Adult Education in Science (Dr. W. A. Waters), 359
Advertisement of Proprietary Medicines, 574
Aerobiology (edited by Forest Ray Moulton), *review* by Prof. R. C. McLean, 258
Aeronautical History : Early American, *review* by Capt. J. L. Pritchard, 461
Aeronautical Medals, 532
Aeronautical Science : Suggested New School of (Sir Stafford Cripps), 686
Aeronautics : Education and Research in, 429
Africa : Barricade against Spread of Rinderpest in, 296
Africa (Southern) : The Bored Stones of, Part 4 (A. J. H. Goodwin), 658
The Bushman Tribes of (A. M. Duggan-Cronin), *review* by Prof. F. Wood Jones, 147
Africa (British West) : Higher Education in (Colonial Office Commission), 211
Africa (West) : Possible Role of Birds in the Maintenance of Yellow Fever in (Brig. G. M. Findlay and Major T. A. Cockburn), 245
African Fishing Industry (South) : Marine Biological Research and the (Dr. Wm. Edwyn Isaac), 515
African Geomorphology, *review* by Dr. P. E. Kent, 59
African Meteorological Workers, 212
African Scenery (South) : (Dr. L. C. King), *review* by Dr. P. E. Kent, 59
Afterglow in High-Pressure Gaseous Discharges (Dr. J. M. Meek and Dr. J. D. Craggs), 538
Agaricaceous Fungi : New British Records for (A. A. Pearson), 633
Agricultural Crops of the United States, *review*, 522
Agricultural Developments in the U.S.S.R. (Sir John Russell), 525
Agricultural Education in the United States (Prof. R. Rae), 166
Agricultural Education (Post-War) : Report of the Luxmoore Committee on, 165
Agricultural Implications : The Atlantic Charter and its, 57
Agricultural Research Council Appointments, 243
Agriculture : Application of Biology to (Dr. Hubert Martin), 532
Agriculture (Food and) : United Nations conference on, 67
Air : Microbiology of the, *review* by Prof. R. C. McLean, 258
Air Filters : Testing and Rating (O. C. Eliason), 167
Air Navigation : Astronomical (Squadron-Leader Ronald Hadingham), *review* by Sir Harold Spencer Jones, 173
Air Transport : International (P E P Broadsheet No. 208), 351
Air and Ocean : Land, (R. P. Beckinsale), *review*, 399
Air-borne Particles by Single Fibres : Electron Microscope Studies of the Capture of (Prof. E. F. Burton), 540 ; *erratum*, 596
Aircraft Industry : Review of the, 270
Alder Leaves (Decaying) : Fungi growing upon (C. T. Ingold), 219
Ale (Nineteenth Century Buns and) : Riboflavin and Vitamin B_1 in (Dr. E. C. Barton-Wright, Dr. T. Moran and H. S. Sarson), 273
Aleutians : Report from the (Major Irving J. Newman), 481
Algæ : Studies in the Comparative Morphology of the (3) (Prof. F. E. Fritsch), 632
Algæ (Red) : Polyploidy in the (Miss Drew), 696
Algebras and their Significance for Physics and Philosophy : The New (Prof. E. T. Whittaker), 603
Alkali Metals : Alloys of Gold with (Dr. A. Sommer), 215
Alloys of Gold with Alkali Metals (Dr. A. Sommer), 215
Alloys (some Iron-Chromium-Nickel) : Crystal Structure, Hardness and Magnetic Properties of (Dr. A. H. Jay), 543
Almanacs and Health Education, 271
Almonds in Great Britain (H. Amphlett Williams), 108
Alps (Eastern) : Earthquake on June 12, 353
Alternators for Switchgear Testing : Design of (V. Easton), 576
Alumina Hydrogel (F. C. Johnson), 415
Alumina-Water : The System (A. W. Laubengayer and R. S. Weisz), 333
Aluminium (Zinc and) : Promotion of the Corrosion of Iron in Alkaline Solutions by (Gustav Nilsson), 189
Aluminizing : Cleaning of Mirrors before (Vladimir Vand), 420
Alvarenza Prize of the College of Physicians of Philadelphia awarded to Dr. Ernest Carroll Faust, 444
Amaravati Sculptures in the Madras Government Museum (C. Sivaramamurti), *review* by E. J. Thomas, 87
Amaryllidaceæ : Scientific Study of the, 481
America : The First Century of Flight in (Jeremiah Milbank, Jr.), *review* by Capt. J. L. Pritchard, 361
Penicillin in, 604
America (Central and South) : Earthquakes in, 410
America (North) : Scientific Societies of, 562
American Aeronautical History : Early, *review* by Capt. J. L. Pritchard, 461
American Anchovies : A Review of the (Samuel F. Hildebrand), 419
American Archæology : Recent Advances in (American Philosophical Society publication), 577
American Army Naturalists, *review*, 61
American Dairy Cattle (E. Parmalee Prentice), *review* by G. E. Fussell, 736
American Education and the War, 184
American Excavations at Thebes, *review* by R. O. Faulkner, 199
American Longevity : Increase in, 443
American Philosophical Society during the Eighteenth and Nineteenth Centuries : The Early History of Science and Learning in America with Especial Reference to the Work of the, 657
American Photographic Information Services in Great Britain : Organization of (Major Irving J. Newman), 481
American Timbers, *review* by Alexander L. Howard, 259
American (Anglo-) Unity and World Peace, 296
American Siphonaptera : North (H. E. Ewing and Irvine Fox), 130
Americas : Sabethine Mosquitoes of the (Dr. John Smart), 279
p-Aminobenzoic Acid on Defective Cultures of Bacteria : Effect of (Dr. J. Ungar), 22
p-Aminobenzoic Acid and Sulphapyridine on Penicillin : Synergistic Effect of (Dr. J. Ungar), 245
α-Amino-*n*-butyric Acid : A Neglected Constituent of Proteins, (Dr. Walter C. Tobie), 249
Amphibian : Effect of Thiourea on the Development of the (Dr. Albert S. Gordon, E. D. Goldsmith and Prof. Harry A. Charipper), 504
Anabiosis in a Soil Ciliate (John M. Watson), 693
Analysis (Chemical) : Optical Methods of (Dr. Thomas R. P. Gibb, Jr.), *review* by Dr. R. A. Morton, 552
Analysis (Inorganic) : Intermediate Qualitative (Dr. A. J. E. Welch), *review*, 492
Analysis (Micro-chemical) : Developments in (E. J. Vaughan), 555
Analysis (Qualitative Inorganic) : A System of (Dr. J. L. B. Smith), second edition, *review*, 613
Analysis : Soil and Plant (Dr. C. S. Piper), *review*, 370,
Analysis of Physical Growth : Factorial (Prof. Cyril Burt), 75
Anatomy : Comparative Vertebrate (Libbie Henrietta Hyman), second edition, *review*, 88
Anatomy of the Dog : Topographical (Dr. O. Charnock Bradley, revised by Prof. Tom Grahame), fourth edition, *review*, 643
Anchovies (American) : A Review of the (Samuel F. Hildebrand), 419
Angels Fear to Tread : Where (Prof. W. E. Allee), 309
Anglo-American Unity and World Peace, 296
Anglo-Portuguese Scientific Relations (Sir George Thomson), 618
Angoumois Grain Moth (*Sitotroga cerealella* Oliv.) : The Development of the (Dr. A. C. Crombie), 246
Animal (Intact) : Single-Fibre Response from an (W. A. H. Rushton and H. B. Barlow), 597
Animal Population of a Seaport, 656
Animal Tissues : Ribonucleic Acids in (Dr. J. N. Davidson and Miss C. Waymouth), 47
Animals with Johne's Disease and Leprosy (Laboratory) : Infection of (John Francis), 250, 449 ; (C. C. Twort), 449
Ankle-Bone of the Ape-Man, *Paranthropus robustus* (Dr. R. Broom), 689
Anthropoid Mandible from Rusinga, Kenya : A Miocene (Dr. L. S. B. Leakey), 319
Anthropological Aspects of the Origins of War (J. R. Swanton), 472
Anthropology : The Future of (Royal Anthropological Institute symposium on), 444, 587
(Prof. W. E. Le Gros Clark), 689
Anthropology in Britain : A Hundred Years of (Sir John Myres) 493,
Anthropology in Colonial Development : The Role of (Lord Hailey), 587
Anthropology in Reconstruction (Prof. F. C. Bartlett), 596, 710
Anthropology in India : Archæology and (Prof. J. H. Hutton), 203
Antibacterial Substance from *Aspergillus clavatus* and *Penicillium claviforme* and its Probable Identity with Patulin (Dr. R. Bergel, A. L. Morrison, A. R. Moss, R. Klein, H. Rinderknecht and J. L. Ward), 750
Antibiotic Substances (Penicillin and other) : Abstracts on (compiled by Miss Muriel E. Whalley), 747
Antifouling Paints (Ships') : Research and (Dr. P. Ewart Bowles), 159 ; (Dr. G. D. Bengough), 159
Ape-Man, *Paranthropus robustus* : An Ankle-Bone of the (Dr. R. Broom), 689
Apparatus (Scientific) : Protective Finishes for, 272
Apparitions (G. N. M. Tyrrell), *review*, 119
Aquatic Fungi : Lower, *review* by Dr. B. Barnes, 462
Aquatic Phycomycetes, exclusive of the Saprolegniaceæ and Pythium (Frederick K. Sparrow, Jr.), *review* by Dr. B. Barnes, 462
Aquilæ : Nova, 444
Arapesh Maternity (R. F. Fortune), 164
Archæological Excavation in Kashmir, 701
Archæological Finds from Greece and Crete, *review* by Prof. R. M. Dawkins, 229
Archæological Finds (New World) : A Synthesis of, 577
Archæological Research in Ulster, 561
Archæological Survey of Pickwick Basin (W. S. Webb, D. L. DeJarnette and others), 360

Archæological Work in Iraq, Palestine, Kenya, Morocco, England, etc. (R. J. Braidwood), 473
Archæologists : Training for (I. A. Richmond), 321 ; (Dr. F. E. Zeuner), 321
  Two Great, *review* by Sir Frederic Kenyon, 673
Archæology : Conference on the Future of (Kathleen M. Kenyon), 320
Archæology : The Future of (Prof. V. Gordon Childe), 587
  Unity of (Prof. V. Gordon Childe), 320
Archæology as a Science (Prof. V. Gordon Childe), 22 ; (J. Reid Moir), 359
Archæology to the Post-War World : Contribution of (Dr. Grahame Clark), 320
Archæology (American) : Recent Advances in (American Philosophical Society publication), 577
Archæology and Anthropology in India (Prof. J. H. Hutton), 208
Archæology and Education, 320
Archegonium in *Pellia epiphylla* : How the Sperm reaches the (Prof. John Walton), 51
Arenaria humifusa Wahlenb., New to the Flora of Spitsbergen : Geographical Distribution of (Dr. Nicholas Polunin), 451
Argentine : Poliomyelitis in the, 297
Armadillidium vulgare Latr. : Length of Life of Sperms in the Woodlouse (H. W. Howard), 331
Army : Education in the, 166
Army (British) : The Story of the (Dr. S. J. Curtis), 166
Arsenious Oxide : Polymorphism of (J. H. Schulman and W. C. Schumb), 754
Art : Impact of Social Influences upon, *review* by F. Ian G. Rawlins, 31
Ascomycetes : Vitamin B_1, Vitamin B_6 and Biotin as Growth Substances for some (Dr. Nils Fries), 105
Ascorbic Acid : Autoxidation of (R. W. Peterson and J. H. Walton), 754
  A Specific Reaction for (Dr. L. F. Levy), 693
  Inhibition of Urease Activity by (L. A. Elson), 49
  Urease Activity and (Dr. J. H. Quastel), 215
Ascorbic Acid Content of Recently Harvested Cereals and Legumes (M. N. Rudra), 78
Ascorbic Acid in Dehydrated Foods (Dr. L. W. Mapson), 13
Ascorbic Acid in the Presence of Sulphur Dioxide : Determination of (Dr. L. F. Levy), 599
Aspergillus : Two New Species of (G. Smith), 633
  A New Species from New Zealand (Anna E. Jenkins and Leon Grodsinsky), 633
Aspergillus clavatus and *Penicillium claviforme* and its Probable Identity with Patulin : An Antibacterial Substance from (Dr. F. Bergel, A. L. Morrison, A. R. Moss, R. Klein, H. Rinderknecht and J. L. Ward), 750
Aspergillus giganteus Wehm.: A Penicillin-like Substance from (Mrs. Flora J. Philpot), 725
Asphyxia : Mass (Dr. K. Simpson), 409
Assay of Riboflavin : Microbiological (Dr. Frank C. Happold), 414 ; (Dr. E. C. Barton-Wright and R. Gordon Booth), 414 ; (Prof. R. H. Hopkins), 724
Astronomer : Saluting an (Joseph R. Habes), 473
Astronomical Air Navigation (Squadron-Leader Ronald Hadingham). *review* by Sir Harold Spencer Jones, 173
Astronomical Interest : Some Old Letters of, 623
Astronomical Work in the U.S.S.R. (Alexander Orlov), 687
Astronomy : An Easy Outline of (Dr. M. Davidson), *review*, 648
  Popular lectures on (Royal Astronomical Society and the British Astronomical Association), 720
Astronomy in Ships' Names, 18
Astronomy in Spanish : General, *review*, 89
Asynapsis in *Rumex Acetosa* : A Y-linked Inheritance in (Dr. Askell Löve), 358
Atlantic (north of Puerto Rico) : Earthquake on July 29, 444
Atlantic (South) east of South Georgia : Earthquake on March 9, 158
Atlantic (Western) : Oysters of the (Richard A. McLean), 419
Atlantic Charter and its Agricultural Implications, 57
Atlas of Stellar Spectra (W. W. Morgan, Philip C. Keenan and Edith Kellman), *review*, 147
Atomic (Sub-) Physics (Prof. Herbert Dingle), *review* by Dr. L. F. Richardson, 7
Atoms (Excited) : The Chemical Reactions of (Dr. E. W. E. Steacie), 362
Australia : Fisheries Research in, 110
  Basic List of the Freshwater Mollusca of (Tom Iredale), 696
  Poisonous and Harmful Fishes of (G. P. Whitley), 534
  St. John's Wort in (R. M. Moore and A. B. Cashmore), 746 ; (F. Wilson and T. G. Campbell), 746
  Scientific and Industrial Research in, 729
  The Termites of (Dr. A. D. Imms), 27
Australian Mullet : Studies in the Biology of, I : Account of the Fishery and Preliminary Statement of the Biology of *Mugil dobula* Gunther (G. L. Kesteven), 110
Australian Region : Termites (Isoptera) from the (Gerald F. Hill), 27
Australian Waters (Southeastern) : Pelagic Tunicates in the Plankton of (Dr. Harold Thompson), 110
Authority in Medicine (Prof. Major Greenwood), 561
Autoxidation of Ascorbic Acid (R. W. Peterson and J. H. Walton), 754
Axis Oppression of Education (Report of the Inter-Allied Information Committee), 169

B. *PROTEUS X Kingsbury* : Relapsing Fever and (Major R. Elsdon-Dew), 565
Bacteria : Effect of *p*-Aminobenzoic Acid on Defective Cultures of (Dr. J. Ungar), 22
  Breakdown of Paraffin Wax by—a Source of Error in Corrosion Tests (T. Howard Rogers), 105
Bacteria in the Bottom Sediments of the Dead Sea (Dr. B. Elazari-Volcani), 274
Bacteria in Potatoes : Spore-forming (Dr. W. J. Dowson), 331
Bacterial Growth (R. M. Lodge and C. N. Hinshelwood), 107
Bacteriological Aspects of Milk Processing (Dr. A. T. R. Mattick), 238
Bacteriostatic Metabolic Products of Moulds : A Suggestion respecting the (Sir Robert Robinson), 162
Bamboo Nails, their Manufacture and Holding Power (V. D. Limaye), 756
Bamboo Pill and Ointment Boxes (Sultan Mohammed), 757
Bamboos in India : Utilization of, 756
Barbarism : The First Stage from, *review* by Miss L. Evelyn Cheesman, 6
Bar-eye Locus in *Drosophila melanogaster* (G. Bonnier, M. Nordenskjöld and G. Bägman), 219
Barometer : History of the (W. E. K. Middleton), 719
  Commemoration of the Invention of the, 718
Barometer Effect of Penetrating Cosmic-Ray Showers (Dr. L. Jánossy and Dr. G. D. Rochester), 445
Bartonellosis : Human (Dr. B. Mera), 360
Beers (War-time) : Riboflavin and Vitamin B_1 in (Prof. R. H. Hopkins), 274
Behaviour : Coat Colour and, 107
Beit Memorial Fellowships for Medical Research : Annual Report of the Trustees, 185
Belgian Public Libraries : Restoration of the (Prof. J. Timmermans), 480
Bell Laboratories Rubber Research Laboratory (F. S. Malm), 157
Beryllium Acetate (Basic) : Change of Symmetry of (Dr. C. A. Beevers), 447
Bible (Real) : In Search of the (A. D. Howell Smith), *review* by the Rev. J. C. Hardwick, 522
Bibliographical References to the Contents of the World's Non-Fiction Literature : A Plan for Mobilizing (Prof. A. F. C. Pollard), 541
Binocular Focusing on a Repeating Pattern (Nellie Henderson), 726
Binocular and Uniocular Threshold of Vision (Dr. Maurice Henri Pirenne), 698
Binucleate Oidia on Binucleate Mycelium of *Polystictus hirsutum* Fr. (S. R. Bose), 508
Bio-Assay (Insecticidal) : Principles of (Dr. H. Hurst), 400
Biochemistry : The Advance of, *review* by Dr. J. H. Quastel, 368
  Annual Review of (edited by James Murray Luck and James H. C. Smith), Vol. 12, *review* by Dr. E. F. Armstrong, 612
Biological Control of the Fly Population in Sewage Filters (T. G. Tomlinson), 52
Biological Control of Insects (Hugh Nicol), *review*, 399
Biological Research in the West Indies (Dr. V. J. Chapman), 47
Biological Statistics : "Student" and the New, *review* by Dr. K. Mather, 551
Biology : Simple Experiments in (compiled by Cyril Bibby), *review*, 614
  Some Aspects of Social (Sir Walter Langdon-Brown), 466
Biology to Agriculture : Application of (Dr. Hubert Martin), 532
Biology of Australian Mullet : Studies in the, I : Account of the Fishery and Preliminary Statement of the Biology of *Mugil dobula* Gunther (G. L. Kesteven), 110
Biology of *Mugil dobula* Gunther : Account of the Fishery and Preliminary Statement of the (G. L. Kesteven), (Studies in the Biology of Australian Mullet, I), 110
Biology in the West Indies : Marine (Prof. C. M. Yonge), 136
Biology and Health : Summer School in (Central Council for Health Education), 271
Biology and Medicine : Microscopic Technique in (Prof. E. V. Cowdry), *review* by Prof. R. C. McLean, 709
Biotin (Vitamin B_1, Vitamin B_6 and) as Growth Substance for some Ascomycetes : (Dr. Nils Fries), 105
Birds in the Maintenance of Yellow Fever in West Africa : Possible Role of (Brig. G. M. Findlay and Major T. A. Cockburn), 245
Birds (British) : Colour Film of (Walter E. Higham), 409
Birth, Poverty and Health (Richard M. Titmuss), *review* by Prof. Lancelot Hogben, 460
Birth-Rate in the United States : Sudden Rise in, 158
Birth-Rates in Germany 50
Bivalents in *Trillium erectum* : Interlocking of (S. G. Smith and E. R. Boothroyd), 219
Blindness : Prevention of (Department of Health for Scotland circular), 297
Blood : The *Rh*-Factor of (P. Levine), 632
Blood of a 48-mm. Embryo : Demonstration of the *Rh*-Factor in the (F. Stratton), 449
Blood (Mammalian) : Siderocytes in (Robert A. M. Case), 599
Blood Corpuscles (Red) : Colour of (Dr. John R. Baker), 331 ; (E. J. Bowen), 476 ; (D. A. Webb), 476 ; (Prof. H. Hartridge), 629
Blood Grouping Technic (Dr. Fritz Schiff and Prof. William C. Boyd), *review* by Dr. John F. Loutit, 520
Blood Groups : The Tharus and their (D. N. Majumdar), 332
Blood Pigments and Related Substances, 714
Body-size, Waking Activity, Size of Eyeballs, and the Origin of Social Life in the Primates : Relation between (Prof. M. F. Ashley Montagu), 573
Boiling Point and Viscosity (Dr. A. H. Nissan), 630
Boiling Point and Viscosity of Gases (Dr. A. Dutta), 445
Bone Growth and the Nervous System : Nutrition in relation to (Sir Edward Mellanby), 111
Books : Rare Scientific (Schuman's Catalogue 8), 562
Books : Recent Scientific and Technical, Supp. ii, July 31 ; Supp. ii, August 28 ; Supp. ii, September 25 ; Supp. ii, October 30 ; Supp. ii, November 27 ; Supp. ii, December 25
Books (Foreign) : Replacement of British Museum's, 595
Bored Stones of Southern Africa (A. J. H. Goodwin), Part 4, 658
Botanical Investigations at Rothamsted : Development of, 91
Bottom Sediments of the Dead Sea : Bacteria in the (Dr. B. Elazari-Volcani), 274
Boxes : Bamboo Pill and Ointment (Sultan Mohammed), 757
Bracken : Rate of Growth of (Prof. K. W. Braid and Elsie Conway), 750
Brazil (Eastern) : A Collection of Freshwater Fishes obtained in (Rodolpho von Ihering), 419
Breakdown of Paraffin Wax by Bacteria—a Source of Error in Corrosion Tests (T. Howard Rogers), 105
Britain : A Hundred Years of Anthropology in (Sir John Myres), 493
  Coal Carbonization and the War and Post-War Economy of (E. V. Evans), 100
  Early, *review* by M. C. Burkitt, 174
  Economics of Reconstruction in, 157
  River Control in, 576
Britain is Governed : How (R. B. McCallum), 193
Britain Needs a National Policy of Technical Education (A Student of the Future), 184
Britain B.C. (S. E. Winbolt), *review* by M. C. Burkitt, 174
Britain (Post-War) : Blue-Prints for, *review* by G. D. H. Cole, 312
Britain's Future Population (R. F. Harrod), 193
  see *also under* Great Britain
British Army : The Story of the (Dr. S. J. Curtis), 166
British Climate and the Space-Heating Engineer (R. Grierson), 213
British Colonial Empire : Future of the (Colonel Oliver Stanley), 71
British Empire : Co-operation in Scientific Research in the, 29
British Isles : A Dental Survey of the (Dr. R. E. G. Armattoe), 630
British Meteor Data : An Analysis of (J. G. Porter), 420

British Museum as a Special Library (F. C. Francis), 481
British Museum's Foreign Books : Replacement of, 595
British Pharmaceutical Codex : Fifth Supplement, 186
British Scientific Instrument Industry, 704
British Soils : Sterol Contents of certain (G. E. Turfitt), 332
British Way : The (Lieut. T. H. Hawkins), 193
British Way in Local Rule (Guy Hunter), 226
British and Russian Men of Science : Exchange of Greetings between, 70
Brompton Hospital Reports, Vol. 11, 1942, *review*, 63
Broadcasting : The Coming-of-Age of (Stuart Hibberd), 622
Brown Medal of the Franklin Institute awarded to Albert Kahn, 45
Budgetary and Dietary Survey of Low-Income Families, Aberdeen, August 1942 (Aberdeen Branch of the Children's Nutrition Council), 223
Buenos Aires : Tuberculosis in (Dr. Alejandro A. Raimondi), 243
Building Industry : Labour in the (P E P Broadsheet No. 212), 562
Building Policy : Post-War, 443
Bulb Correction in Capillary Tube Viscometry (Dr. R. K. Schofield and Dr. G. W. Scott Blair), 477
Bulb Formation and Flower Production in Onion Plants Grown from Sets (O.V.S. Heath and M. Holdsworth), 334
Buns and Ale (Nineteenth Century) : Riboflavin and Vitamin B_1 in (Dr. E. C. Barton-Wright, Dr. T. Moran and H. S. Sarson), 273
Burma : Pleistocene Molluscs of (J. Bequaert), 335
    Pleistocene Period in (Dr. Hellmut de Terra), 335
    Pleistocene Vertebrates of (Edwin H. Colbert), 335
    Research on Early Man in (M. C. Burkitt), 335
    Stone Age Industries in (Hallam L. Movius, Jun.), 335
Bursahom, Kashmir : The Megaliths of (Dr. Hellmut de Terra), 701
Busbar Protection (M. Kaufmann and W. Szwander), 220
Bushman Tribes of Southern Africa (A. M. Duggan-Cronin), *review* by Prof. F. Wood Jones, 147
Butanol-Acetone Fermentation : Mechanism of the (Dr. E. Simon), 626
Bute : The Highland Border Series in (J. G. C. Anderson), 277

CABLE (Buried) : Lightning Protection of (E. D. Sunde), 425
Cable Ratings (Electric Power) : Graphical Determination of (H. Waddicor), 195
Cacao : Thrips Resistance in (Dr. E. McC. Callan), 332
    Witches' Broom Disease of (R. E. D. Baker and S. H. Crowdy), 361
Cacao Tannin (E. C. Humphries), 569
Calcium (Magnesium-) Antagonism in Muscle (Dr. G. D. Greville and Dr. H. Lehmann), 81
Calculus: The Operational (Prof. H. T. H. Piaggio), 93
California (Gulf of) : Earthquake on June 14, 353
Californian Coast : Shell Fish-hooks of the (Eugene Robinson), 419
Calycanine : Constitution of (Dr. A. Hargreaves), 603
Cambridge Greensand : Erratics of the (L. Hawkes), 512
Cambridgeshire and the Isle of Ely : The Place-Names of (P. H. Reaney), *review* by M. C. Burkitt, 145
Camera (Giant) installed in the Photocopy Department of the Bell Laboratories (Richard Haard), 335
Camouflage : Physiological Basis of, 605
Canada : Gold and Iron Prospects in (Prof. M. B. Baker), 362
    Vital Statistics of, 186
Canada (United States and) : Handbook of Scientific and Technical Societies and Institutions of the (U.S. National Research Council), fourth edition, 562
Canadian Schoolchildren : A Survey of (Dr. R. E. G. Armattoe), 391
Cancer Research, 26
Cancer Research : Abstracts from, Vol. 1, 1941, 212
Cancer (Treatment of) by Fast Neutrons (Dr. L. H. Gray and Dr. J. Read), 53
Cannibalism (Prof. J. H. Hutton), 381
Capillaries : Flow of Visco-Elastic Materials in (A. C. Merrington), 663
Capillary Tube Method : Measurement of Anomalous Viscosity by the (A. C. Merrington), 214
Capillary Tube Viscometry : Bulb Correction in (Dr. R. K. Schofield and Dr. G. W. Scott Blair), 477
Capture of Air-borne Particles by Single Fibres : Electron Microscope Studies of the (Prof. E. F. Burton), 540 ; *erratum*, 596
Carbides used for Tool-tips (Sintered) : X-Rays in the Study of (L. D. Brownlee), 543
Carbon Dioxide Bands at $2{\cdot}01\mu$ and $2{\cdot}05\mu$ in the Solar Spectrum : Resolution of the (A. Adel), 361
Carbohydrate Metabolism : Vitamin C and (Sachchidananda Banerjee), 329
Carbon Dioxide to Species Hybrids in Drosophila : Transmission of Susceptibility to (Dr. H. Kalmus), 692
Carboy : Surface 'Memory' in a (Herman A. Liebhafsky and Lester B. Bronk), 695
Carcinogenic Hydrocarbons : Aqueous Soap Solutions of (Dr. Stephan Beck), 537
    Relative Potency of (Dr. W. R. Bryan and Dr. M. B. Shimkin), 360
Carnivorous Plants (Dr. Francis Ernest Lloyd), *review*, 63
Caroline Islands : Earthquake on March 15, 101
γ Cassiopeiæ : Gradients and Colour-Temperatures of (D. L. Edwards), 697
Cat (Dog and) : A Nuclear Ring in the Developing Male Germ Cells of the (Prof. J. Bronte Gatenby), 79
Catalase : Decomposition of Hydrogen Peroxide by (Prof. D. Keilin and Dr. E. F. Hartree), 626
Catalytically Active Centres on Surfaces : Distribution of (Dr. F. H. Constable), 135
Cathode Ray Oscillograph in Industry (Dr. W. Wilson), *review* by Dr. L. E. C. Hughes, 147
Cathode Ray Oscillograph Traces : Recording, 656
Cation-active Salts and Sodium Hexametaphosphate (Long-Chain) : Reaction between (Dr. J. Powney), 76
Cattle : American Dairy (E. Parmalee Prentice), *review* by G. E. Fussell, 736
    Intracutaneous Injection of (W. M. Henderson), 629
Cell : Distribution of Nucleic Acid in the (H. G. Callan), 503 ; (Dr. Edgar Stedman and Dr. Ellen Stedman), 503
Cell (Malignant) : A Speculation on the Nature of the Chemical Structure which is the Essence of the (H. Donovan and Dr. D. L. Woodhouse), 509
Cell Migration in the Adrenal Cortex of Rats : Trypan Blue and (Italo Calma and Charles L. Foster), 536
Cellulose (Native) : Molecular Weight of (Nils Gralén and Prof. The Svedberg), 625
Cellulose Acetate Moulds : Recording Low Relief in Metallic Surfaces by (Capt. A. T. J. Dollar), 248
Centenary : The Rothamsted (H. V. Garner), 128
Centenary of the *Economist*, 324
Centenary of the S.S. *Great Britain*, 74
Cepheid Variables and Novæ : Theory of (F. Hoyle and R. A. Lyttleton), 333
Ceramics for High-Frequency Insulation (M. D. Rigterink), 453
Cereals and Legumes (Recently Harvested) : Ascorbic Acid Content of (M. N. Rudra), 78
Ceylon, Mauritius and Malaya : Labour Conditions in (Major G. St J. Orde Browne), 203
Challenge of Peace, 281
Chance : Time and, the Story of Arthur Evans and his Forebears (Joan Evans), *review* by Sir Frederic Kenyon, 673
Chemical Analysis : Optical Methods of (Dr. Thomas R. P. Gibb, Jr.), *review* by Dr. R. A. Morton, 552
Chemical Background for Engine Research (edited by R. E. Burk and Oliver Grummitt), *review* by Prof. D. M. Newitt, 675
Chemical Composition and Nutritive Value of Milk and Milk Products (Dr. S. K. Kon), 238
Chemical Control of Mitosis (Dr. P. T. Thomas and R. Drew), 564
Chemical Evolution of the Ocean (Prof. E. J. Conway), 511
Chemical Industries (edited by L. Ivanovszky), eighteenth edition, *review*, 613
Chemical Nature of Chromosomes (Dr. H. C. Choudhuri), 475
Chemical Physics : Introduction to (Prof. J. C. Slater), *review* by Sir Ralph Fowler, 488 ; *erratum*, 562
Chemical Reactions of Excited Atoms (Dr. E. W. R. Steacie), 362
Chemical Structure which is the Essence of the Malignant Cell : A Speculation on the Nature of the (H. Donovan and Dr. D. L. Woodhouse), 509
Chemistry : Optical Methods in, *review* by Dr. R. A. Morton, 552
Chemistry for 1942 : Annual Report on the Progress of, Vol. 39, *review*, 648
Chemistry in the Nineteenth Century : Some Czechoslovak Contributions to (Dr. Gerald Druce), 239
Chemistry (Analytical) : Future of, 185
Chemistry : Intermediate (Prof. T. M. Lowry and A. C. Cavell), third edition, *review*, 613
Chemistry (Organic) : An Introduction to (Dr. J. W. Baker), *review*, 90
    Keeping Up With, *review* by Prof. John Read, 586
    A Text-Book of (the late Dr. Julius Schmidt), English edition by Dr. H. Gordon Rule, fourth edition, revised and extended, *review* by Prof. John Read, 174
    A Text-Book of (Prof. John Read), third edition, *review* by Dr. E. R H. Jones, 613
    Theoretical (Dr. J. B. Cohen), revised edition by Dr. P. C. Austin, *review* by Dr. E. R. H. Jones, 90
Chemistry (Physical) : A Treatise on, Vol. 1 : Atomistics and Thermodynamics, edited by Prof. Hugh S. Taylor and Prof. Samuel Glasstone, third edition, *review* by Sir Ralph Fowler, 200
    For Students of Biochemistry and Medicine (Prof. Edward Staunton West), *review*, 63
Chemoreceptivity in Drosophila : Localization in (Michael Begg and Prof. Lancelot Hogben), 535 ; *erratum*, 562
Chemotherapy : Recent Advances in (Sir Henry Dale), 500
Chemotherapy (Local) : Wound Infections and (Prof. G. B. Reed), 362
Chestnuts as Food for Pigs (Horse) : Value of (R. Braude), 571
Chicama, Moche, and Virú Valleys, Peru : Skeletal Remains from Cultural Associations from the (T. D. Stewart), 332
Chick Embryo : Human Poliomyelitis in the Developing (Sven Gard), 660
Child (Mother and) : War-Time Food for (Dr. Geoffrey Bourne), *review*, 371
Children (Papuan) : Mid-dorsal Hair Whorls in (Dr. Frank Fenner), 538
Children (Toronto Elementary School) : A Height and Weight Survey of, 1939 (N. Keyfitz), 391
Chile : Earthquake on April 6, 213
China : Poverty and Progress in (P E P Broadsheet No. 209), 380
China (Free) : Parasitological Research in (K. Chang), 699
    Parasitology in (Dr. G. Lapage), 699
China (South-West) : Science in, 1 : The Physico-Chemical Sciences (Dr. Joseph Needham), 9 ; 2 : The Biological and Social Sciences (Dr. Joseph Needham, 36
China Sea (South) west of the Philippine Islands : Earthquake on June 8, 186
China's Health Problems (Dr. Szeming Sze), 719
Chinese Medical Journal, 719
Chinese University Students : Aid for (International Student Service Committee), 73
Chree Lecture of the Physical Society (Brigadier B. F. J. Schonland), 46
Chree Medal of the Physical Society for 1943 awarded to Brigadier B. F. J. Schonland, 46
Christianity and Truth : Science, (Dr. Julian S. Huxley), 79 ; (Dr. Norman R. Campbell), 192 ; (C. D. Hardie), 192 ; (Dr. C. Berkeley), 479
Chromatography : Principles and Practice of (Prof. L. Zechmeister and Dr. L. Cholnoky, translated from the second and enlarged German edition by A. L. Bacharach and F. A. Robinson), second impression, *review*, 35
    Theory of (D. de Vault), 220
Chromosome Arm : Interspecific Translocation of a (A. Håkonsson), 511
42-Chromosome Wheat : A Synthesis of a, 575
Chromosomes : Chemical Nature of (Dr. H. C. Choudhuri), 475
    Chromosomin, a Protein Constituent of (Dr. E. Stedman and Mrs. Ellen Stedman), 267
Chromosomin, a Protein Constituent of Chromosomes (Dr. E. Stedman and Mrs. Ellen Stedman), 267
Chromospheric Eruptions : Movements in (M. A. Ellison), 697
Chungking : Science in (Dr. Joseph Needham), 64
Ciencia, 382
Ciliate (Soil) : Anabiosis in a (John M. Watson), 693
Cinematograph Films of Growing Crystals (C. W. Bunn), 543
Circuits : Time Base, *review* by L. Bainbridge-Bell, 116
Circumference of the Earth : Eratosthenes and the, 473
Citizen : The Young (Dr. A. E. Morgan), 456
Citizenship (World) : Social Studies and (L. J. F. Brimble and Frederick J. May), *review* by J. A. Lauwerys, 339

Civil Service : A Staff College for the, 99
Civilian Contribution to Education in the Forces, 307
Clarke Memorial Medal for 1942 of the Royal Society of New South Wales awarded to Dr. W. L. Waterhouse, 131
Class and Mating in the Evolution of Man : Race, (Dr. C. D. Darlington), 315
Clifton Park System of Farming and Laying Down Land to Grass (Robert H. Elliot), fifth edition, *review*, 737
Climate and the Space-Heating Engineer : British (R. Grierson), 213
Clocks : Short-Period Erratics of Free Pendulum and Quartz (W. M. H. Greaves and L. S. T. Symms), 633
Clover Hybrids : Sweet (W. K. Smith), 696
Club-Root of Swedes due to a Seed-borne Infection : A Case of (Dr. L. G. G. Warne), 509
Coagulation of Colloids (Prof. Eric K. Rideal), 618
Coal : Research on, 323
Coal Carbonization and the War and Post-War Economy of Britain (E. V. Evans), 100
Coal Research : Coke and (Prof. H. L. Riley), 323 ; (Dr. R. A. Mott), 323
Coals (Small) : Utilisation of (British Coal Utilisation Research Association conference on), 213
Coat Colour and Behaviour, 107
Cocksfoot Grass (A. Müntzing), 333
Coelomomyces Keilin : Germination of the Sporangia of (Dr. Botha De Meillon and J. Muspratt), 507
Cœnobitidæ : Paguridæ and (Dr. E. F. Thompson), 363
Coke and Coal Research (Prof. H. L. Riley), 323 ; (Dr. R. A. Mott), 323
Colchicine Alone and Combined with X-Rays on Paramecium : Influence of (L. Halberstaedter and A. Back), 275
Cold-worked Metals : New X-Ray Evidence of the Nature of the Structural Changes in (Dr. H. Lipson and A. R. Stokes), 20
Collaboration in World Affairs : Functional, 671
College : A National Administrative Staff, 100, 472
Colleges (Technical) : Future of (R. M. Barrer and J. P. Andrews), 387 ; (Dr. D. S. Anderson), 388 ; (Lawrence W. Kershaw and D. Humphrey), 388 ; (Dr. H. Schofield and H. Garratt), 450
  Future of, 519
  University of London External Examinations and the (Sir E. Graham-Little), 478
Colloid Systems : Kinetics of (Prof. S. S. Joshi), 618
Colloids : Coagulation of (Prof. Eric K. Rideal), 618
Colonial Development : The Role of Anthropology in (Lord Hailey), 587
Colonial Economic Advisory Committee, 325
Colonial Empire (British) : Future of the (Colonel Oliver Stanley), 71
Colonial Fisheries Advisory Committee : Appointment of a, 501
Colonial Labour and Social Development (Prof. Daryll Forde), 203
Colonial Service Appointments and Promotions: 18, 101, 213, 353, 473, 624
Colonies : Higher Education in the (Colonial Office Commission), 211
  Potato Eyes as readily transportable 'Seed' for the (Sir Geoffrey Evans), 464
Colonies (Crown) : Nutritional Research in the (D. Fitzgerald Moore), 418
Coloration of Lepidoptera (Cryptic) : Stereomorphism in (Dr. B. N. Schwanwitsch), 508
Colorimetry of *B8–B9* Stars : Photo-electric (V. Nikonov and E. Brodskaja), 746
Colour of Ferrocyanide Crystals (H. E. Williams), 220
Colour of Red Blood Corpuscles (Dr. John R. Baker), 331 ; (E. J. Bowen)' 476 ; (D. A. Webb), 476 ; (Prof. H. Hartridge), 629
Colour (Petal-) Inheritance in Lychnis (H. G. Baker), 161
Colour Microscopy in Ultra-Violet Rays (E. M. Brumberg), 357
Colour-Temperatures of γ Cassiopeiæ : Gradients and (D. L. Edwards), 697
Colour Vision : Physiology of (A. H. S. Holbourn), 190 ; (Prof. H. Hartridge), 190 ; (E. N. Willmer), 190
Colour-blind Men in Great Britain : Distribution of (P. E. Vernon and A. Straker), 690
Comet Comas-Sola : Rediscovery by Miss Oterma, 502
Comet Daimaca : Orbit computed by Mr. Naur, 596
Comet Daniel (1909 IV) : Rediscovery of, (G. F. Kellaway), 747
Comet Oterma, 1943*a* : Orbit for, 444
Comets at Riverview College Observatory : Photographic Observations of (D. J. K. O'Connell), 697
Commercial Policy of the United Kingdom : Trade Regulations and (Research Staff of the National Institute of Economic and Social Research), *review* by Prof. J. G. Smith, 521
Commonwealth (Threefold) : Peace and the (T. G. Jones), 351
Communication (Electrical) : Wave Guides in (J. Kemp), 701
Compounds (Organic) : Dictionary of (Prof. I. M. Heilbron and H. M. Bunbury), Vol. I : Abietic Acid—Dypnone, new, revised and enlarged edition, *review* by Prof. John Read, 586
Consumer Needs in Economic Stability, 365
Context (Dissonance and) : Relation between (P. A. D. Gardner and Dr. R. W. Pickford), 358 ; (C. G. Gray), 570 ; (Dr. R. W. Pickford), 570
Control of the Fly Population in Sewage Filters : Biological (T. G. Tomlinson), 52
Control of Insects : Biological (Hugh Nicol), *review*, 399
Control of Mitosis : Chemical (Dr. P. T. Thomas and R. Drew), 564
Cooking (Old-time) : Fermented Liquors in (H. S. Sarson), 386
Co-operation in Scientific Research in the British Empire, 29
Copley Medal of the Royal Society awarded to Sir Joseph Barcroft, 559, 665
Cormack Bequest to the Royal Society of Edinburgh, 130
Coronal Line Spectrum (P. Swings), 754 ; (Edlén, —.), 754
Correspondence : An Eighteenth Century (Prof. H. C. Plummer), 623
Corrib (River) : Salmon of the, together with Notes on the Growth of the Brown Trout in the Corrib System (Arthur E. J. Went), 332
Corrosion of Iron in Alkaline Solutions by Zinc and Aluminium : Promotion of the (Gustav Nilsson), 189
Corrosion Tests (A Source of Error in) : Breakdown of Paraffin Wax by Bacteria—(T. Howard Rogers), 105
Corticium (*Rhizoctonia*) *Solani* : Sharp Eyespot of Wheat caused by (Mary D. Glynne and Wendy M. Ritchie), 161
Cosmic-Ray Showers (Penetrating) : Barometer Effect of (Dr. L. Jánossy and Dr. G. D. Rochester), 445
Costa Rica : Earthquake on July 4, 410
Couch Grass, *Agropyron repens*, Beauv. : A Periclinal Division in the 'Dermatogen' at the Growing Point of (Dr. B. C. Sharman), 276
Cows (Dairy) : Stimulation of the Milk Production of, by Feeding Thyroid-active Iodinated Proteins (K. L. Blaxter), 751
Cow's Milk : Xanthine Oxidase Activity of (Alastair N. Worden), 505
Crabs (Hermit) from the John Murray Expedition, 363
Craniata : Conception of the Tail in the (Beni Charan Mahendra), 163
Creative Demobilisation, Vol. I : Principles of National Planning (E. A. Gutkind) ; Vol. 2 : Case Studies in National Planning (edited by E. A. Gutkind), *review* by D. J. Morgan, 256
Crep's : Phylogeny and Basic Number in (H. A. Tobgy), 753
Cresson Medal of the Franklin Institute awarded to Prof. Charles M. Allen, 45
Crete (Greece and) : Archæological Finds from, *review* by Prof. R. M. Dawkins, 229
Croonian Lecture of the Royal Society (Sir Edward Mellanby on Nutrition in relation to Bone Growth and the Nervous System), 111
Crop Plants (Roots of) : Competition for Nitrogen between the Take-all Fungus and the (S. D. Garrett), 417
Crops : Field (Prof. Howard C. Rather), *review*, 522
Crops of the United States : Agricultural, *review*, 522
Crops and Vegetables (Root) : The Production of Seed of (Imperial Agricultural Bureaux), 410
Crustacea : A New Order of, 167
Crystal Harmonics for Oscillator Control : High (I. E. Fair), 363
Crystal Surfaces : An Interferometric Procedure for the Examination of (Dr. S. Tolansky), 722
Crystallography (X-Ray) : Summer School in, 381
Crystals : Thermal Scattering of X-Rays by (G. H. Begbie and Prof. Max Born), 19 ; (Dr. K. Lonsdale), 20
Crystals (Ferrocyanide) : Colour of (H. E. Williams), 220
Crystals (Growing) : Cinematograph Films of (C. W. Bunn), 543
Cultural Change in Painting : The Psychology of (Dr. R. W. Pickford), *review* by F. Ian G. Rawlins, 31
Culture and Manual Skill (C. W. Hansel), 513
Cultures of Bacteria (Defective) : Effect of *p*-Aminobenzoic Acid on (Dr. J. Ungar), 22
Cuscatlan Bridge in El Salvador, 381
Cuticle (Insect) : Pore Canals of the (R. Dennell), 50
Cyprus : Sulphur Springs of (Dr. M. Tamari), 277
Cyst Technique for the Potato Strain of the Eelworm *Heterodera schachtii* Schmidt (Gemmell Single) : A Modification of the (Dr. C. Ellenby), 133
Czechoslovak Contributions to Chemistry in the Nineteenth Century : Some (Dr. Gerald Druce), 239

DAIMACA, Comet : Orbit computed by Mr. Naur, 596
Dandelions (Rubber-yielding) in Sweden, 131
Daniel (1909 IV), Comet : Rediscovery of (G. F. Kellaway), 747
Darwin and 'Water-Bloom' (T. John Hart), 661
Davy Medal of the Royal Society awarded to Prof. I. M. Heilbron, 559, 666
Daylight : Photography of Stars in (M. Waldmeier), 158
Daylight Rays (Ultra-Violet and) : Variations of (Dr. J. R. Ashworth), 330
Dead Sea : Bacteria in the Bottom Sediments of the (Dr. B. Elazari-Volcani), 274
  A Dimastigamœba in the Bed of the (Dr. B. Elazari-Volcani), 301
Decarboxylase : *l*-Lysine—Preparation of Specific Enzyme and Coenzyme (Ernest F. Gale and Helen M. R. Epps), 327
Decay and Insect Damage in Timbers for Aircraft and other Purposes : Recognition of (Bulletin of the Department of Scientific and Industrial Research), 18
Deccan (Maharashtra) : Studies in Prehistory of the (H. D. Sankalia), 746
Decomposition of Hydrogen Peroxide by Catalase (Prof. D. Keilin and Dr. E. F. Hartree), 626
Deep-Focus Earthquakes and Aftershocks (Ross R. Heinrich), 25
Degradation of 1, 3 Polysaccharides : Regulated (Dr. Vincent C. Barry), 537
Dehydrated Foods : Ascorbic Acid in (Dr. L. W. Mapson), 13
Dehydration of Food by Radio-Frequency Energy (Vernon W. Sherman), 560
Deir el Bahri, 1911–1931 : Excavations at (H. E. Winlock), *review* by R. O. Faulkner, 199
Demobilization : Aspects of (Sir William Jowitt), 72
  Creative, Vol. I : Principles of National Planning (E. A. Gutkind) ; Vol. 2 : Case Studies in National Planning (edited by E. A. Gutkind), *review* by D. J. Morgan, 256
Demobilization of Scientific and other Personnel : Post-War (Committee of Inquiry appointed by the Minister of Labour and National Service), 100
Democracy : Discipline for (T. V. Smith), *review* by T. Raymont, 284
Democracy (Fascism and) : Science under (Association of Scientific Workers, West Midland Area, conference on), 186, 306
Density of Certain Marine Organisms (A. G. Lowndes), 511
Dental Malocclusion in the Quintuplets (N. Ford and A. D. Mason), 361
Dental Survey of the British Isles (Dr. R. E. G. Armattoe), 630
'Dermatogen' at the Growing Point of Couch Grass, *Agropyron repens*, Beauv. : A Periclinal Division in the (Dr. B. C. Sharman), 276
Detector : A New Tuned Null (F. B. Anderson), 361
Determination of the Velocity of Sound : An Oscillographic Method for the (J. M A. Lenihan), 661
Deuterium Fluorides (Hydrogen and) : Polymerization of (R. W. Long, J. H. Hildebrand and W. E. Morrell), 420
Development of International Organization : Functional, 309
Developments in the U.S.S.R. : Agricultural (Sir John Russell), 525
Devon : A Family of (Dr. Vaughan Cornish), *review*, 371
Diagnosis of Our Time (Karl Mannheim), *review* by Prof. George Catlin, 287
Diagnosis of Typhus Fever by Rickettsial Agglutination : Specific (Prof. I. J. Kligler and E. Olejnik), 627
Diamonds : Artificial Production of (Dr. C. H. Desch), 148
  J. B. Hannay and the Artificial Production of (Lord Rayleigh), 597 ; (Prof. M. W. Travers), 726
Diapause in the Eggs of a Grasshopper (H. E. Andrewartha), 107
Dibenzanthracene Mouse Sarcoma : Long-term Cultivation *in vitro* of a (Dr. F. Jacoby), 299
Dictionary of Science and Technology in English–French–German–Spanish (Dr. Maxim Newmark), *review*, 709
Dictionary of Science and War : An Encyclopædic (Surgeon Rear-Admiral C. M. Beadnell), *review* by Dr. L. E. C. Hughes, 119

Diet of Wood Pigeons, 533
Dietary Survey (Budgetary and) of Low-Income Families, Aberdeen, August, 1942 (Aberdeen Branch of the Children's Nutrition Council), 223
Dimastigamœba in the Bed of the Dead Sea (Dr. B. Elazari-Volcani), 301
Digestibility of Oatmeal Phytin by Adult Man (E. W. H. Cruickshank, J. Duckworth, H. W. Kosterlitz and G. M. Warnock), 384
Digestive Glands : Secretory Mechanism of the (Prof. B. P. Babkin), 363
Diphtheria : The Epidemiology of (W. T. Russell), 561
Directory : A Scientific (Dr. James Walker), 752
Discipline for Democracy (T. V. Smith), *review* by T. Raymont, 284
Disease : Industrial Health and (London School of Hygiene and Tropical Medicine week-end course on), 325
Disease of Cacao : Witches' Broom (R. E. D. Baker and S. H. Crowdy), 361
Diseases : Plant, 425
Diseases of Vegetables (Donald E. Green), *review*, 491
Diseases (Tropical) : Modern Drugs and (Dr. F. Hawking), 204
Disintegration in a Wilson Chamber (Nuclear) : Photograph of a (M. Sinha), 568
Dissonance and Context : Relation between (P. A. D. Gardner and Dr. R. W. Pickford), 358 ; (C. G. Gray), 570 ; (Dr. R. W. Pickford), 570
Distribution (Geographical) of *Arenaria humifusa* Wahlenb., New to the Flora of Spitsbergen (Dr. Nicholas Polunin), 451
Distribution Plant and Mains on A.C. Networks : Maintenance of (F. N. Beaumont and F. A. Geary), 747
Diurnal Activity of Three Insect Pests of Stored Products (Dr. R. F. Ewer), 133
Dog : Topographical Anatomy of the (Dr. O. Charnock Bradley, revised by Prof. Tom Grahame), fourth edition, *review*, 648
Dog and Cat : A Nuclear Ring in the Developing Male Germ Cells of the (Prof. J. Bronte Gatenby), 79
Donnan Membrane Equilibrium (S. G. Chaudhury), 76
Drosophila : Localization of Chemoreceptivity in (Michael Begg and Prof. Lancelot Hogben), 535 ; *erratum*, 562
    Transmission of Susceptibility to Carbon Dioxide to Species Hybrids in (Dr. H. Kalmus), 692
Drosophila melanogaster : Bar-eye Locus in (G. Bonnier, M. Nordenskïöld and G. Bägman), 219
Drosophilo pseudo-obscura : High Rate of Mutation of (K. Mampell), 696
Drug Action : Modes of (Faraday Society discussion on), 298, 495
    Permeability and Molecular Constitution as Factors in (Dr. H. Hurst), 292
Drug Addicts : Narcotic (Dr. Michael J. Pescor), 297
Drugs : Actions of (Prof. J. H. Gaddum), 495
Drugs and Tropical Diseases : Modern (Dr. F. Hawking), 204
Duddell Medal of the Physical Society awarded to John Guild, 686
Dynamics in Psychology (Wolfgang Koehler), *review* by A. W. Wolters, 172
Dynamics (Galactic) : Recent Advances in (Prof. A. C. Banerji), *review*, 492
Dystrophy (Progressive Muscular) : On Pseudohypertrophic and Allied Types of (Julia Bell), *review* by Dr. F. W. Sansome, 260

EAR : Sensitivity of the (W. A. Munson), 453
Early Scientific Works (Davis and Orioli Catalogue No. 8), 473
Earth : Eratosthenes and the Circumference of the, 473
Earth' in the U.S.S.R. ('Scorched) : Rehabilitation of the, 424
Earth Tremors in Portugal on June 22, 74
Earth and Man (Prof. Darrell Haug Davis), *review*, 147
Earthquake : in the Eastern Alps on June 12, 353
    in the Atlantic north of Puerto Rico on July 29, 444
    in the south Atlantic east of South Georgia on March 9, 1[illegible]
    in the Gulf of California on June 14, 353
    in the Caroline Islands on March 15, 101
    in Chile on April 6, 213
    in the South China Sea west of the Philippine Islands on June 8, 186
    in Costa Rica on July 4, 410
    north-east of Fiji on March 15, 101
    in Germany on May 28, 45
    in Hokkaido Island, Japan, on June 13, 353
    in the Indian Ocean on July 23, 444
    in the West Indies on July 30, 444
    in Jamaica on July 16, 186
    in Japan on September 10, 324
    in the Kamchatka Peninsula on August 10, 444
    near the east coast of the Kamchatka Peninsula on March 7, 158
    in the bed of Lake Erie on March 9, 158
    north-east of the Macquarie Islands on September 6, 720
    in Mexico on February 22, 272
    in the Molucca Passage on September 5, 720
    in New Guinea on March 21, 101
    in the Pacific on March 15, 101 ; on March 21, 101 ; on June 15, 353
    in the Pacific Ocean west of California on September 10, 720
    in the Pacific Ocean off the south-west coast of Guatemala on August 31, 624
    in the Pacific Ocean near the east coast of Kamchatka on March 7, 158
    in the Pacific Ocean west of the Marianas Islands on April 9, 213
    in the Pacific Ocean west of Mexico on September 20, 720
    in the Pacific Ocean between Samoa and the Friendly Islands on September 11, 720
    in Peru on June 30, 410
    off the coast of Peru on July 5, 410
    off the north-west coast of Porto Rico on September 10, 720
    south-west of Samoa on March 15, 101
    at San Francisco on October 26, 720
    in the Sulu Sea north-east of Borneo on June 9, 186
    in Turkey on June 20, 17, 382
    in Turkey : The Recent (Ernest Tillotson), 684
Earthquakes : in Central and South America, 410
    near the Ecuador-Colombia Border during May, June and July 1942, 25
    Recent, 158, 186, 444
    during June, 353 ; during July and August, 624 ; during September, 720
    registered at Kew during May, 45 ; during June, 353 ; during July, 624 ; during August, 624 ; during September, 720
    registered in New Zealand during 1941, 111 ; during February, 18 ; during March, 74 ; during April, 213
    registered in Spain during May and June, 382
    registered at Stonyhurst during May, 45 ; during June, 353
    registered at Toledo during August, 624
    registered at Wellington, New Zealand, during July, 624
Earthquakes and Aftershocks : Deep-Focus (Ross R. Heinrich), 25
Eclipse of the Moon on August 15, 131
Eclipse of the Sun : on August 1, 131
    on September 21, 1941, in the U.S.S.R., 658
Ecological Principles in Forestry Practice (L. A. Harvey), 196
Economic Advisory Committee : Colonial, 325
Economic Reconstruction (J. R. Bellerby), Vol. I, *review* by G. D. H. Cole, 312
Economic Stability : Consumer Needs in, 365
Economics : Engineering (Sir Frank Gill), 272
Economics of Reconstruction in Britain, 157
Economist : Centenary of the, 324
Economy of Britain (War and Post-War) : Coal Carbonization and the (E. V. Evans), 100
Economy in Yunnan (Rural) : Three Types of (Li-Yu-I, Hsiaotung Fei and Tse-yi-Chang), 195
Ecuador-Colombia Border : Earthquakes during May, June and July 1942, 25
Education : Axis Oppression of (Report of the Inter-Allied Information Committee), 169
    Post-War World (Dr. Grahame Clark), 500
Education in the Army, 166
Education in the Forces : Civilian Contribution to, 307
    Report of the Central Advisory Council, 307
    Adult (Major J. O. R. Phillips and Dr. S. J. Curtis), 166
Education in Science : Adult (Dr. W. A. Waters), 359
Education for Whom and for What ?, 4
Education After the War (Association of University Professors and Lecturers of the Allied Countries in Great Britain conference on), 221
Education for World Citizenship, *review* by J. A. Lauwerys, 339
Education in World Ethics and Science (Sir Richard Gregory), *review* by T. Raymont, 284
Education (Agricultural) in the United States (Prof. R. Rae), 166
Education (Post-War Agricultural). : Report of the Luxmoore Committee on, 165
Education (American) and the War, 184
Education (Engineering) : Reconstruction of, 609
Education : Forestry, 197
Education (Health) : Almanacs and, 271
Education (Higher) : in the Colonies (Colonial Office Commission), 211
    in British West Africa (Colonial Office Commission), 211
Education (Technical) : Britain Needs a National Policy of (A Student of the Future), 184
Education : Archæology and, 320
Education in Great Britain : Industry, Research and, 579
Education : Science, Religion and, *review* by T. Raymont, 284
Education Scheme : A Part-time (Henley's Telegraph Works Co. Ltd.), 410
Education and Research in Aeronautics, 429
Education and Training for Engineers (Institution of Electrical Engineers report), 137
Education and the United Nations (Report of a Joint Commission of the London International Assembly and Council for Education in World Citizenship), 169
Education of the Allied Governments (Ministers of), Conference of : Message of sympathy to the University of Oslo, 717
Educational Reconstruction, 120 ; (General Review), 393 ; (2), 427 (3). The Needs of Youth, 455 ; (4) Adult Education, 483 ; (5), 517 ; (6) Science as an Educational Discipline, 545
    in Europe, 169
    Inter-Allied Bureau for, 444
Educational Reconstruction and its Impact on Training for Mechanical Engineering: The White Paper on (Institution of Mechanical Engineers), 609
Educational Research : Foundation for, 717
Eelworm *Heterodera schachtii* Schmidt : A Modification of the Gemmell Single Cyst Technique for the Potato Strain of the (Dr. C. Ellenby), 133
Eighteenth Century Correspondence : An (Prof. H. C. Plummer), 623
El Salvador : The Cuscatlan Bridge in, 381
Elderberries to Poultry : Feeding Horse Chestnuts and (H. Temperton), 345
Electric Power Cable Ratings : Graphical Determination of (H. Waddicor), 195
Electrical Communication : Wave Guides in (J. Kemp), 701
Electrical Distribution (Rural) : Protective Systems for (Institution of Electrical Engineers symposium on), 26
Electrical Properties of Soil at a Wave-length of 5 Metres (Frequency 60 Mc./s.) : The Determination of the (Dr. J. S. McPetrie and J. A. Saxton), 84
Electrical Responses from the Primary Acoustic Centre of the Frog (J. Ek and C. L. v. Euler), 132
Electrical Supply : Maintenance Work in, 747
Electrical Testing Applied to Insulated Wires : A New Method of (H. A. Macdonald and E. C. R. Scarfe), 51
Electricity in Mines (J. A. B. Horsley), 747
Electromagnetic Frequencies : Ultra-High (Dr. G. C. Southworth), 54
Electron Microscope Studies of the Capture of Air-borne Particles by Single Fibres (Prof. E. F. Burton), 540 ; *erratum*, 596
Electrophoresis : Variation of Serum Composition with the Age of Horses as shown by (Dr. Alfred Polson), 413
Elliptic Functions (Jacobian) : Notation of (Prof. E. H. Neville), 108
Elm Tree: The (Alexander L. Howard), 636
Ely (Isle of) : The Place-Names of Cambridgeshire and the (P. H. Reaney), *review* by M. C. Burkitt, 145
Embryo (48-mm.) : Demonstration of the *Rh*-Factor in the Blood of a (F. Stratton), 449
Embryo (Developing Chick) : Human Poliomyelitis in the (Sven Gard), 660
Emigration : Population and, *review* by Prof. H. J. Fleure, 60
Empiricism : Logical, *review* by Prof. Herbert Dingle, 397
Employment : Post-War (E. S. Conway), 642

Employment (Full) : The Foreign Balance and (T. Balogh), 560
  Housing, Town Planning and (F. J. Osborn), 443
Employment Policy and Organization of Industry after the War (Nuffield College Statement), 367
Emulsions : Practical (H. Bennett), *review* by Dr. A. E. Alexander, 371
Encyclopædia of Substitutes and Synthetics (edited by Morris D. Schoengold), *review*, 709
Energy : James Prescott Joule and the Unit of (Prof. H. S. Allen), 354 ; (A. W. V. Mace), 418 ; (Graham Renshaw), 418 ; (J. H. Awbery), 479 ; (W. and R. Chambers, Ltd.), 479 ; (Prof. J. B. S. Haldane), 479 ; (Dr. K. R. Webb), 602 ; (Prof. C. H. Lees), 602 ; (Prof. W. Peddie), 602
Engine Research : The Chemical Background for (edited by R. E. Burk and Oliver Grummitt), *review* by Prof. D. M. Newitt, 675
Engineer (Space-Heating) : Brtish Climate and the (H. Grierson), 213
Engineering in Early Warfare (R. P. Howgrave-Graham), 596
Engineering : Fluid Mechanics and Statistical Methods in (Hugh L. Dryden, Theodore von Kármán, Anton A. Kalinske, Thomas K. Sherwood, Samuel S. Wilks, Walter A. Shewhart, Leslie E. Simon and Roscoe Pound), *review*, 119
Engineering (Mechanical) : The White Paper on Educational Reconstruction and its Impact on Training for (Institution of Mechanical Engineers), 609
Engineering Economics (Sir Frank Gill), 272
Engineering Education : Reconstruction of, 609
Engineering Information : Sources of, 186
Engineers : Education and Training for (Institution of Electrical Engineers report), 137
English : The Writing of, *review* by Dr. E. H. Tripp, 645
Eznymes by Irradiation : Inactivation of (Dr. G. Goldhaber and Dr. J. Leibowitz), 274
Enzymology and Related Subjects : Advances in (edited by F. F. Nord and C. H. Werkman), Vols. 1, 2 and 3, *review* by Dr. J. H. Quastel, 368
Eratosthenian Averages (Aurel Wintner), *review* by Prof. G. H. Hardy, 708
Eratosthenes and the Circumference of the Earth, 473
Erie (Lake) : Earthquake on March 9, 158
Erratics of Free Pendulum and Quartz Clocks : Short-Period (W. M. H. Greaves and L. S. T. Symms), 633
Erythrocytes in Hypotonic Saline : Fragility of (A. C. Roy), 599
Ethics and Science (World) : Education in (Sir Richard Gregory), *review* by T. Raymont, 284
Ethylenebiguanide : Composition and Constitution of (Prof. P. Ray), 694
Etiology of Paroxysmal Tachycardia (Dr. Richard F. Öhnell), 216
Europe : Educational Reconstruction in, 169
  Post-War Nutritional Relief in, 615
  Post-War Relief in, 634
  Production of Rubber in, 747
Europe after the War of 1914–18 : Relief in, 194
Europe (Central) : Economic and Technical Reconstruction in (F. Nemec), 621
Europe (Freed) : Problems of—the Challenge to Medical Sciences (Association of Scientific Workers conference on), 634
Europe (Post-War) : Food and Farming in (P. Lamartine Yates and D. Warriner), *review*, 399
Evolution of Man : Race, Class and Mating in the (Dr. C. D. Darlington), 315
Evolution of the Planetary System (Lieut.-Colonel K. E. Edgeworth), 251
Excavations at Deir el Bahri, 1911–1931 (H. E. Winlock), *review* by R. O. Faulkner, 199
Excavations at Thebes : American, *review* by R. O. Faulkner, 199
Explosions (Gaseous) : Temperature Gradients in (Dr. A. S. Leah), 303
Eye-balls and the Origin of Social Life in the Primates (Body-size, Waking Activity, Size of) : Relation between (Prof. M. F. Ashley Montagu), 573
Eyespot (Sharp) of Wheat caused by *Corticium* (*Rhizoctonia*) *Solani* (Mary D. Glynne and Wendy M. Ritchie), 161

FACTORIAL Analysis of Physical Growth (Prof. Cyril Burt), 75
Faith and Works (Lionel Curtis), 282
Families (Low-Income) : Needs of (D. Caradog Jones), 223
Family Meals : Sociological Value of (Prof. J. H. S. Bossard), 271
Farming in Post-War Europe : Food and (P. Lamartine Yates and D. Warriner), *review*, 399
Farming and Laying Down Land to Grass : The Clifton Park System of (Robert H. Elliot), fifth edition, *review*, 737
Fascism and Democracy : Science under (Association of Scientific Workers, West Midland Area, conference on), 186, 306
Feeding in Great Britain (Planned) : Four Years of (Alan Blainey), 191 ; (Dr. Magnus Pyke), 191
Feeding Apparatus of Biting Flies, 632
Feeding Horse Chestnuts and Elderberries to Poultry (H. Temperton), 345
Fermentation (Butanol-Acetone) : Mechanism of the (Dr. E. Simon), 626
Fermented Liquors in Old-time Cooking (H. S. Sarson), 386
Ferrocyanide Crystals : Colour of (H. E. Williams), 220
Fever (Relapsing) and *B. proteus X Kingsbury* (Major R. Elsdon-Dew), 565
Fever in West Africa (Yellow) : Possible Role of Birds in the Maintenance of (Brig. G. M. Findlay and Major T. A. Cockburn), 245
Fibre (Single-) Response from an Intact Animal (W. A. H. Rushton and H. B. Barlow), 597
Fibres under the X-Rays : Textile (Dr. W. T. Astbury), *review* by F. Ian G. Rawlins, 90
Field Crops (Prof. Howard C. Rather), *review*, 522
Field-Strength Measuring Equipment : The Design of Ultra-Short Wave (F. M. Colebrook and A. C. Gordon-Smith), 83
Fiji (north-east of) : Earthquake on March 15, 101
Films of Growing Crystals : Cinematograph (C. W. Bunn), 543
Films (Cine-) : Science Class Lecture (Thomas S. Wylie), 623
Films in Optical Instruments (Non-Reflecting) : Principles of the Use of (Dr. K. M. Greenland), 290
Filters (Air) : Testing and Rating (O. C. Eliason), 167
Filtration of Sewage Sludge : Vacuum (J. M. Wishart, C. Jepson and L. Klein), 249 ; (J. H. Garner), 418
Fire Resistance of some Indian Timbers : Studies in (D. Narayanamurti and R. Gopalachari), 605
Firmamento, El. (Rev. Luis Rodés), segunda edición, *review*, 89
Firmness' of Soft Bodies : A New Criterion for Expressing the 'Intensity of (Dr. G. W. Scott Blair), 412
Fish (Freshwater) : Observations on Some Phases of the Life Cycle of *Ichthyophthirius multifiliis* Fouquet 1876, a Ciliate Protozoan Parasite of (A. Dunbavin Butcher), 753
Fish in Palestine (Freshwater) : Production of (C. C. Ricardo Bertram), 415
Fish Gate : The (Michael Graham), *review* by Sir D'Arcy W. Thompson, 647
Fisheries of Mauritius : Appointment of Dr. J. F. G. Wheeler as marine biologist, 408
Fisheries Advisory Committee (Colonial) : Appointment of a, 501
Fisheries Research in Australia, 110
Fishes of Australia : Poisonous and Harmful (G. P. Whitley), 534
Fishes from the Phœnix and Samoan Islands (Leonard P. Schultz), 511
Fishes (Florida) : Notes on (Henry W. Fowler), 419
Fishes obtained in Eastern Brazil (Freshwater) : A Collection of (Rodolpho von Ihering), 419
Fish-hooks of the Californian Coast : Shell (Eugene Robinson), 419
Fishing Industry (South African) : Marine Biological Research and the (Dr. Wm. Edwyn Isaac), 515
Flagellate Organisms : The Term *Tractellum* in (A. G. Lowndes), 51
Flaking of Flint : High-Angle Edge (J. Reid Moir), 78 ; (Alfred S. Barnes), 477 ; (D. F. W. Baden-Powell), 663 ; (Henry Bury), 664
Flame Gases : Temperature of (Prof. W. T. David), 278
Flavelle Medal of the Royal Society of Canada awarded to Prof. B. P. Babkin, 362
Fleas of North America, 130
Flies (Biting and Disease-carrying) : The Mouth-parts of (R. E. Snodgrass), 632
Flight in America : The First Century of (Jeremiah Milbank, Jr.), *review* by Capt. J. L. Pritchard, 461
Flint : High-angle Edge Flaking of (J. Reid Moir), 78 ; (Alfred S. Barnes), 477 ; (D. F. W. Baden-Powell), 663 ; (Henry Bury), 664
Flora of Spitsbergen : Geographical Distribution of *Arenaria humifusa* Wahlenb., New to the (Dr. Nicholas Polunin), 451
Floras of the World : Geographical Guide to the, Part I : Africa, Australasia, Insular Floras, North America and South America (S. F. Blake and Alice C. Atwood), *review* by Dr. W. A. Sledge, 202
Florida Fishes : Notes on (Henry W. Fowler), 419
Flow of Visco-Elastic Materials in Capillaries (A. C. Merrington), 663
Flow of Viscous Fluids (A. Fathy, S. Bishara and S. A. M. Hassanein), 512
Flow Pattern of Gases in Furnaces : Use of Radon to Trace the (R. Mayorcas and M. W. Thring), 723
Flow States in Emergent Gas Streams (J. E. Garside, A. R. Hall and Prof. D. T. A. Townend), 748
Flower Production in Onion Plants Grown from Sets : Bulb Formation and (O. V. S. Heath and M. Holdsworth), 334
Fluid Mechanics and Statistical Methods in Engineering (Hugh L. Dryden, Theodore von Kármán, Anton A. Kalinske, Thomas K. Sherwood, Samuel S. Wilks, Walter A. Shewhart, Leslie E. Simon and Roscoe Pound), *review*, 119
Fluids (Viscous) : Flow of (A. Fathy, S. Bishara and S. A. M. Hassanein), 512
Fluorescence of Organic Molecules (Dr. Joseph Weiss), 176
Fly Population in Sewage Filters : Biological Control of the (T. G. Tomlinson), 52
Focusing on a Repeating Pattern : Binocular (Nellie Henderson), 726
Folk-lore : Laryngology and (Dr. J. D. Rolleston), 212
Food for Mother and Child : War-Time (Dr. Geoffrey Bourne), *review*, 371
Food for Pigs : Value of Horse Chestnuts as (R. Braude), 571
Food by Radio-Frequency Energy : Dehydration of (Vernon W. Sherman), 560
Food Consumption in Sweden during 1942–43 : Rations and (Carin Boalt and Yngve Zotterman), 635
Food Products (Stored) : Common Insect Pests of (Dr. H. E. Hinton and Dr. A. Steven Corbet), 272
  Taxonomy of the Moths Infesting (Dr. A. Steven Corbet), 742
Food Situation in Sweden, 213
Food and Agriculture : United Nations conference on, 67
Food and Farming in Post-War Europe (P. Lamartine Yates and D. Warriner), *review*, 399
Food and the Strategy of Peace, 1
Foods (Dehydrated) : Ascorbic Acid in (Dr. L. W. Mapson), 13
Foodstuffs : Apparent Vitamin C in Certain (Dr. Frank Wokes, Joan G. Organ, Jeanette Duncan and Dr. F. C. Jacoby), 14
Forces : Civilian Contribution to Education in the, 307
Forces (H.M.) : Adult Education in (Major J. O. R. Phillips and Dr. S. J. Curtis), 166
  Education in (Report of the Central Advisory Council), 307
Foreign Balance and Full Employment (T. Balogh), 560
Foreign Trade and Tariffs, *review* by Prof. J. G. Smith, 521
Forest Policy in Great Britain : Post-War, 337
Forest Products : Utilization Investigations of, 242
Forestry : Seed Selection in (Prof. H. G. Champion), 354
Forestry Education, 197
Forestry Practice : Ecological Principles in (L. A. Harvey), 196
Forward—By the Right (Tory Reform Committee), 744
Forward with Science (Prof. Rogers D. Rusk), *review* by Prof. J. A. Crowther, 341
Fourier Analysis to Twenty-Nine Harmonics : Numerical (Dr. M. A. S. Ross), 302 ; (Dr. D. Macewan and Dr. C. A. Beevers), 303
Franklin Medals of the Franklin Institute awarded to Prof. Harold C. Urey and to Dr. George Washington Pierce, 45
Free Will Controversy (Dr. M. Davidson), *review* by Prof. H. Dingle, 229
Freedoms of Science (Sir Robert Watson-Watt), 543
Frequency Modulation (K. R. Sturley), *review*, 175
Freshwater Fish in Palestine : Production of (C. K. Ricardo Bertram), 415
Freshwater Fishes obtained in Eastern Brazil : A Collection of (Rodopho von Ihering), 419
Freshwater Mollusca of Australia : Basic List of the (Tom Iredale), 696
Frictional Properties of Metallic Films (Dr. Robert Schnurmann), 247 ; (Dr. T. P. Hughes and J. L. Heaton), 247
Frog : Electrical Responses from the Primary Acoustic Centre of the (J. Ek and C. L. v. Euler), 132
Frost Resistance : The Mechanism of (Prof. G. W. Scarth), 363
Fruit Production, 24
Fuel Research : Collaboration in, 532
  Standing Consultative Conference on, Preliminary Meeting, 532
Fuel Research in Great Britain : Government, 718

Fungi : A Dictionary of the (Dr. G. C. Ainsworth and Dr. G. R. Bisby). *review*, 614
  Lower Aquatic, *review* by Dr. B. Barnes, 462
  Taxonomy and Distribution of the (Dr. G. R. Bisby and Dr. G. C. Ainsworth), 633
Fungi growing upon Decaying Alder Leaves (C. T. Ingold), 219
Fungi (Agaricaceous) : New British Records for (A. A. Pearson), 633
Fungicides : Silver Compounds as (Lowell W. Nielsen), 511
Fungus and the Roots of Crop Plants (Take-all) : Competition for Nitrogen between the (S. D. Garrett), 417
Furnaces : Use of Radon to Trace the Flow Pattern of Gases in (R. Mayorca and M. W. Thring), 723
Future : A Technologist Looks at the (Dr. C. R. Burch), 523
  Science, Religion and the (Rev. Charles E. Raven), *review* by T. Raymont, 284

GALACTIC Clusters : Photographic Survey of (George Alter), 220
Galactic Dynamics : Recent Advances in (Prof. A. C. Banerji), *review*, 492
Gas Industry in Great Britain (P E P Broadsheet No. 210), 352
Gas Streams (Emergent) : Flow States in (J. E. Garside, A. R. Hall and Prof. D. T. A. Townend), 748
Gaseous Discharges (High-Pressure) : Afterglow in (Dr. J. M. Meek and Dr. J. D. Craggs), 538
Gaseous Explosions : Temperature Gradients in (Dr. A. S. Leah), 303
Gases : Boiling Point and Viscosity of (Dr. A. Dutta), 445
Gases in Furnaces : Use of Radon to Trace the Flow Pattern of (R. Mayorcas and M. W. Thring), 723
Gases (Flame) : Temperature of (Prof. W. T. David), 278
Gem Testing for Jewellers (B. W. Anderson), *review*, 6
Gemmell Single Cyst Technique for the Potato Strain of the Eelworm *Heterodera schachtii* Schmidt : A Modification of the (Dr. C. Ellenby), 133
Genetics of the Mouse (Dr. Hans Grüneberg), *review* by Dr. C. H. Waddington, 585
Genotype of some *Rh*-Positive People : A Serum that Discloses the (Dr. R. R. Race and Dr. G. L. Taylor), 300
Genotypes in Man (*Rh*) : Recognition of (Dr. R. R. Race, Dr. G. L. Taylor, Miss Kathleen E. Boorman and Miss Barbara E. Dodd), 563
Geographical Distribution of *Arenaria humifusa* Wahlenb., New to the Flora of Spitsbergen (Dr. Nicholas Polunin), 451
Geographical Guide to the Floras of the World, Part I : Africa, Australasia, Insular Floras, North America and South America (S. F. Blake and Alice C. Atwood), *review* by Dr. W. A. Sledge, 202
Geography : The Regional Concept in (W. Fitzgerald), 740
Geography and International Settlement (W. Fitzgerald), 589
Geography (Historical Plant) : An Introduction to (E. V. Wulff), *review* by Dr. H. Godwin, 490
Geography (Plant) : Polyploidy and (A. and D. Löve), 219
Geology in the War and After (Dr. E. B. Bailey), 728
Geology and Health (C. E. N. Bromehead), 224
Geomagnetism : Edmond Halley and (Prof. S. Chapman), 231 ; *erratum*, 298
  The Solar Corona and (M. Waldmeier), 44
Geomorphology : African, *review* by Dr. P. E. Kent, 59
Geranylamine Hydrochloride : Structure of (L. Bateman and Dr. G. A. Jeffrey), 446
German publications being reproduced in the United States (H. K. Lewis and Co. Ltd.'s list), 720
German for the Scientist (Chemist and Physicist) (Peter F. Wiener), *review*, 35
Germany : Birth-Rates in, 502
  The Problem of (Royal Institute of International Affairs), 310
  (west of Balingen near Stuttgart) : Earthquake on May 28, 45
Germination of Seeds : Appearance of Glutathione during the Early Stages of the (Sir Frederick Gowland Hopkins and Edward James Morgan), 288
Germination of the Sporangia of Cœlomomyces Keilin (Dr. Botha De Meillon and J. Muspratt), 507
Ghost Formation : Tablet Absorption and (Dr. S. J. Folley), 134
Giant Strain of *Torulopsis utilis* : Preparation of a (Dr. A. C. Thaysen and Muriel Morris), 526
Glass Tubes (Small) : Reverberation in (Shaun M. Cox), 357
Glevum and the Second Legion, Part I (Charles Green), 219
Glow Discharges : Initiation of (Dr. J. D. Craggs and Dr. J. M. Meek), 386
Glutathione during the Early Stages of the Germination of Seeds : Appearance of (Sir Frederick Gowland Hopkins and Edward James Morgan), 288
Glycogen in Adipose Tissue after Insulin Injection (Prof. E. Wertheimer), 565
Glycosides and Sugars : Configuration of (E. M. Montgomery, N. K. Richtmyer and C. S. Hudson), 361
Gold with Alkali Metals : Alloys of (Dr. A. Sommer), 215
Gold and Iron Prospects in Canada (Prof. M. B. Baker), 362
Golgi Element in the Renal Tubule : Apparent Reversal of Position of the (Major J. F. A. McManus), 417
Gonadotrophin (Mares' Serum) : Purification of (Dr. C. Rimington and I. W. Rowlands), 355
Goraghwood Quarry, Co. Armagh : Granitization of Hornfelsed Sediments of (Doris L. Reynolds), 420
Government (Local) : Reconstruction of, 113
Grã-Bretanha (Portugal e a) : Relaçoes cientificas entre (Prof. H. Amorim Ferreira), 618
Granitization of Hornfelsed Sediments (Doris L. Reynolds), 420
Granular Solids : Rugosity of (Robert H. S. Robertson and Barbara S. Emödi), 539
Grass : Cocksfoot (A. Müntzing), 333
Grass (Laying Down Land to) : The Clifton Park System of Farming and (Robert H. Elliot), fifth edition, *review*, 737
Grasshopper : Diapause in the Eggs of a (H. E. Andrewartha), 107
Grassland Research in the United States (Prof. D.B. Johnstone-Wallace), 165
Great Britain : Organization of American Photographic Information Services in (Major Irving J. Newman), 481
  Almonds in (H. Amphlett Williams), 108
  Distribution of Colour-blind Men in (P. E. Vernon and A. Straker), 690
  Four Years of Planned Feeding in (Alan Blainey), 191 ; (Dr. Magnus Pyke), 191
  Post-War Forest Policy in, 337
  Government Fuel Research in, 718
  The Gas Industry in (P E P Broadsheet No. 210), 352
  Industrial Research in, 16
  Industry, Research and Education in, 579
  Library Service in, 733
  Plans for Reconstruction in, 225
  A Minister of Reconstruction in, 594
  Scientific Research in, 129
  The Social Sciences in, 669
  Importation of Technical Literature into (Dr. K. R. Webb, E. W. Balson, S. H. Harper and Dr. I. G. M. Campbell), 479
  Post-War Needs of Universities in, 595
  Conservation of Wild Life in (Universities' Federation for Animal Welfare), 443
  see also under Britain
Great Britain : Centenary of the S.S., 74
Greece and Crete : Archæological Finds from, *review* by Prof. R. M. Dawkins, 229
Growth : Bacterial (R. M. Lodge and C. N. Hinshelwood), 107
Growth (Physical) : Factorial Analysis of (Prof. Cyril Burt), 75
Growth of Schoolboys : War-time (E. M. Billington, Dr. R. A. McCance and E. M. Widdowson), 187
Growth Substances for some Ascomycetes : Vitamin B_1, Vitamin B_6 and Biotin as (Dr. Nils Fries), 105
Guam : Insects of (Dr. A. D. Imms), 55
Guinea Pigs : Vitamin P Deficiency in (Dr. Geoffrey H. Bourne), 659
Guinea Pigs (Rabbits and) : Water Requirements of (Prof. E. L. Kennaway), 157
Gyroscopic Principles and Applications (Prof. C. E. Inglis), 502

HAIR Whorls in Papuan Children : Mid-dorsal (Dr. Frank Fenner), 538
Halley Lecture (Prof. S. Chapman), 231 ; *erratum*, 298
Hamilton's Quaternions : The Significance and Development of (Prof. H T. H. Piaggio), 553
  Issue of special postage stamps by the Government of Eire in celebration of, 553
  Royal Irish Academy Meeting in celebration of, 688
Hamster (Syrian) : Vitamin C Requirements of the (Dr. Donald F. Clausen and Prof. William G. Clark), 300
Hannay (J. B.) and the Artificial Production of Diamonds (Lord Rayleigh), 597 ; (Prof. M. W. Travers), 726
Harmonics or Oscillator Control : High Crystal (I. E. Fair), 363
Hawksley Lecture of the Institution of Mechanical Engineers (Prof. C. E. Inglis), 502
h/e : Short Wave-length Limit of the Continuous X-Ray Spectrum and Determinations of (Per Ohlin), 329
Health : Inter-Allied Charter of (Anglo-Czechoslovak Founders Committee prizes for essays on an), 534
Health of New Zealand, 158
Health (Biology and) : Summer School in (Central Council for Health Education), 271
Health : Birth, Poverty and (Richard M. Titmuss), *review* by Prof. Lancelot Hogben, 460
Health : Geology and (C. E. N. Bromehead), 224
Health (Public) : in Honduras (Dr. P. H. Ordónez Dias), 101
  in Peru (Dr. Manuel Prado), 297
  in Uruguay (Dr. J. C. Mussio Fournier), 352
Health Advisory Councils : Local Industrial, 17
Health Education : Almanacs and, 271
Health Measures (Public) : Recent Advances in, 561
Health Services (Public) : Report on the Reform of (Sir Arthur McNalty), 442
Health and Disease : Industrial (London School of Hygiene and Tropical Medicine week-end course on), 325
Heating : Area (Dr. L. E. C. Hughes), 497
Heating in New York : District, 500
Heats of Formation : Steric Hindrance and (Dr. A. G. Evans and Prof. M. Polanyi), 738
Hemp (Indian) : Physiologically Active Fractions of (B. C. Bose and Dr B. Mukerji), 109
Henderson Medal of the Franklin Institute awarded to Mr. Harry Miller Pflager, 45
Hermaphroditos, the Human Intersex (Dr. A. P. Cawadias), *review*, 614
Heterochromatin as a Specific Character : Amount of (Dr. M. J. D. White), 536
Heterostylism (D. Lewis), 753
High-Frequency Insulation : Ceramics for (M. D. Rigterink), 453
Highland Border Series in Bute (J. G. C. Anderson), 277
Histone as a Regulator of Mitosis : Probable Function of (Dr. E. Stedman and Mrs. Ellen Stedman), 556
Historical Development of Microbiological Methods in Vitamin Research (Dr. Mary Sandford), 374
Hokkaido Island, Japan : Earthquake on June 13, 353
Hollong (*Dipterocarpus macrocarpus*) Sleepers (Green) : Treatment of (D. Narayanamurti), 242
Homes (People's) : An Enquiry into (Mass-Observation Report), *review* by Lieut. T. H. Hawkins, 257
Honduras : Public Health in (Dr. P. H. Ordónez Dias), 101
Hormone Therapy (Sex) : A Glossary of Terms used in (*Pharmaceutical Journal*), 534
Hormones of the Pituitary Gland : Protein, 360
Hornfelsed Sediments : Granitization of (Doris L. Reynolds), 420
Horse Chestnuts as Food for Pigs : Value of (R. Braude), 571
Horse Chestnuts and Elderberries to Poultry : Feeding (H. Temperton), 345
Horses (Variation of Serum Composition with the Age of) as shown by Electrophoresis (Dr. Alfred Polson), 413
Host Plant : Sex Ratio affected by (E. McC. Callan), 162
Housing of Scientific Societies, 703
Housing, Town Planning and Full Employment (F. J. Osborn), 443
Hughes Medal of the Royal Society awarded to Prof. M. L. E. Oliphant, 559, 667

Human Bartonellosis (Dr. B. Mera), 360
Human Physiology (Kenneth Walker), *review*, 648
Human Poliomyelitis in the Developing Chick Embryo (Sven Gard), 660
Humus in Tropical Soils : Conservation of (Dr. A. Sreenivasan), 572
Huxley Memorial lecture of the Royal Anthropological Institute (Prof. F. C. Bartlett), 596, 710
Hydrocarbons (Carcinogenic) : Aqueous Soap Solutions of (Dr. Stephan Beck), 537
  Relative Potency of (Dr. W. R. Bryan and Dr. M. B. Shimkin), 360
Hydrogel : An Alumina (F. C. Johnson), 415
Hydrogen Exchange Reactions (H. V. A. Briscoe and co-workers), 757
Hydrogen Peroxide by Catalase : Decomposition of (Prof. D. Keilin and Dr. E. F. Hartree), 626
Hydrogen and Deuterium Fluorides : Polymerization of (R. W. Long, J. H. Hildebrand and W. E. Morrell), 420
Hygrometry with a Wet-Bulb : Precision (Dr. W. Lawrence Balls), 389
Hypotonic Saline : Fragility of Erythrocytes in (A. C. Roy), 599

I*CHTHYOPHTHIRIUS multifiliis* Fouquet 1876 : Observations on Some Phases of the Life Cycle of (A. Dunbavin Butcher), 753
Identification of Male Schistosomes in Uncommon Sites (Dr. F. Gordon Cawston), 477
Immunisation : Studies on, First Series (Sir Almroth E. Wright), *review*, 614
Immunochemistry : Recent Advances in (Dr. W. T. J. Morgan), 82
Importation of Technical Literature into Great Britain (Dr. K. R. Webb, E. W. Balson, S. H. Harper and Dr. I. G. M. Campbell), 479
Inactivation of Enzymes by Irradiation (Dr. G. Goldhaber and Dr. J. Leibowitz), 274
Income : Homes and, *review* by Lieut. T. H. Hawkins, 257
India : Archæology and Anthropology in (Prof. J. H. Hutton), 208
  Utilization of Bamboos in, 756
  Scientific Work in (Sir Lewis Fermor), 656
  Organization of Scientific and Industrial Research in, 639
Indian Hemp : Physiologically Active Fractions of (B. C. Bose and Dr. B. Mukerji), 109
Indian Ocean : Earthquake on July 23, 444
Indian Timbers : Studies in Fire Resistance of some (D. Narayanamurti and R. Gopalachari), 605
Indian Woods : Types of Timber Seasoning Kilns suitable for Drying (M. A. Rehman), 242
Indies (East) : Islands and Peoples of the (Raymond Kennedy), 688
Indies (West) : Biological Research in the (Dr. V. J. Chapman), 47
  Earthquake on July 30, 444
  Marine Biology in the (Prof. C. M. Yonge), 136
  Staphylinidæ of the (Richard E. Blackwelder), 219
Industrial Health Advisory Councils : Local, 17
Industrial Health and Disease (London School of Hygiene and Tropical Medicine week-end course on), 325
Industrial Mycology : An Introduction to (George Smith), second edition, *review* by Dr. J. Grainger, 173
Industrial Psychology : An Introduction to (Dr. May Smith), *review* by Dr. Millais Culpin, 230
Industrial Research in Great Britain, 16
Industrialization in China, 380
Industry : The Cathode Ray Oscillograph in (Dr. W. Wilson), *review* by Dr. L. E. C. Hughes, 147
  X-Rays in, *review* by Dr. W. A. Wood, 145
Industry after the War : Employment Policy and Organization of (Nuffield College Statement), 367
Industry After the War, Who is Going to Run It ? (Charles Madge, in consultation with Donald Tyerman), 459
Industry of Plastics : Science and, *review*, 398
Industry (Research and) : X-Rays in (Dr. H. Hirst), *review* by Dr. W. A. Wood, 145
Industry, Research and Education in Great Britain, 579
Industry and Society, I : Relation to the Nation, 458 ; (2) Relation to Government, 486
Infant Mortality, *review* by Prof. Lancelot Hogben, 460
Infection of Laboratory Animals with Johne's Disease and Leprosy (John Francis), 250, 449 ; (C. C. Twort), 449
Infection (Seed-borne) : A Case of Club-Root of Swedes due to a (Dr. L. G. G. Warne), 509
Infections (Wound) and Local Chemotherapy (Prof. G. B. Reed), 362
Information (Specialised) : ASLIB War-Time Guides to British Sources of, No. 5, Engineering other than Electrical, 186
Information Council : An International (Prof. A. F. C. Pollard), 541
Information Services for the Scientist (J. G. Crowther), 480
Inheritance of Asynapsis in *Rumex Acetosa* : A Y-linked (Dr. Askell Löve), 358
Inheritance in Lychnis : Petal-Colour (H. G. Baker), 161
Inhibition of Urease Activity by Ascorbic Acid (L. A. Elson), 49
Inhibition of Urease by Penicillin (Lt.-Col. Joseph C. Turner, Capt. Frederick K. Heath and Boris Magasanik), 326
Injection of Cattle : Intracutaneous (W. M. Henderson), 629
Inorganic Analysis (Qualitative) : Intermediate (Dr. A. J. E. Welch), *review*, 492
  A System of (Dr. J. L. B. Smith), second edition, *review*, 613
Insect Cuticle : Pore Canals of the (R. Dennell), 50
Insect Damage in Timbers for Aircraft and other Purposes : Recognition of Decay and (Bulletin of the Department of Scientific and Industrial Research), 18
Insect Enemies of Lac : Control of the (P. S. Negi), 639
Insect Pests of Stored Products (Three) : Diurnal Activity of (Dr. R. Ewer), 133
Insect Pests of Stored Food Products : Common (Dr. H. E. Hinton and Dr. A. Steven Corbet), 272
Insecta Pterygota into Subordinate Groups : Subdivision of (Dr. B. N. Schwanwitsch), 727
Insecticidal Bio-Assay : Principles of (Dr. H. Hurst), 400
Insects : The Biological Control of (Hugh Nicol), *review*, 399
Insects of Guam (Dr. A. D. Imms), 55
Insects as a Source of Vitamins : Intracellular Symbionts of (Dr. G. Fraenkel and M. Blewett), 506
Instrument Transformers (A. Hobson), 696
Instruments (Optical) : Principles of the Use of Non-Reflecting Films in (Dr. K. M. Greenland), 290
Insulated Wires : A New Method of Electrical Testing, Applied to (H. A. Macdonald and E. C. R. Scarfe), 51
Insulating Papers : Acid Neutralization in (D. A. McLean), 140
Insulation : Ceramics for High-Frequency (M. D. Rigterink), 453
Insulin : Manufacturers to standardize colour and style of packings of, 534
Insulin Colour Code, 656
Insulin Injection : Glycogen in Adipose Tissue after (Prof. E. Wertheimer), 565
Integration of Research Activities in the United States : War and Post-War (Dr. R. H. Heindel), 212
'Intensity of Firmness' of Soft Bodies : A New Criterion for Expressing the (Dr. G. W. Scott Blair), 412
Interferometric Procedure for the Examination of Crystal Surfaces (Dr. S. Tolansky), 722
Interlocking of Bivalents in *Trillium erectum* (S. G. Smith and E. R. Boothroyd), 219
International Air Transport (P E P Broadsheet No. 208), 351
International Auxiliary Language : Otto Jespersen and an (H. Jacob), 324
International Information Council : An (Prof. A. F. C. Pollard), 541
International Languages (E. T. Harris), 601
International Mineral Control : Problems of, 607
International Organization : Functional Development of, 309
International Settlement : Geography and (W. Fitzgerald), 589
International Trade : New Plans for (Institute of Statistics, Oxford, Supplement to Bulletin No. 5, Vol. 5), 560
Intersexuality in Melandrium (D. Löve), 220
Intracutaneous Injection of Cattle (W. M. Henderson), 629
Iodinated Proteins (Thyroid-active) : Stimulation of the Milk Production of Dairy Cows by Feeding (K. L. Blaxter), 751
Ion Clusters by X-Rays : Production of (U. Fano), *erratum*, 186
Iron in Alkaline Solutions by Zinc and Aluminium : Promotion of the Corrosion of (Gustav Nilsson), 189
Iron (Cast) : Welding of (J. G. Pearce), 25 ; (W. J. Driscoll), 25
Iron Excretion and Metabolism in Man (Dr. R. A. McCance and Dr. E. M. Widdowson), 326
Iron Utilization : Inefficiency of, 361
Iron–Chromium–Nickel Alloys : Crystal Structure, Hardness and Magnetic Properties of some (Dr. A. H. Jay), 543
Iron Prospects in Canada : Gold and (Prof. M. B. Baker), 362
Iron-Silicon System : Structure of the Eta Phase of the (Madame A. R. Weill), 413
Iron and Steel Industry : The Spanish, 755
Irradiation : Inactivation of Enzymes by (Dr. G. Goldhaber and Dr. J. Leibowitz), 274
Island of New Guinea (Miss L. Evelyn Cheesman), 41
Islands and Peoples of the East Indies (Raymond Kennedy), 688
Isolated Muscle and Isolated Strips of Myosin : Relation between Experiments on (Major Inderjit Singh), 132
Isolation of Seed Crops : Spatial (Gordon Haskell), 591
Isoptera (Termites) from the Australian Region (Gerald F. Hill), 27
Italy : Preservation of Museums in, 472

JACOBIAN Elliptic Functions : Notation of (Prof. E. H. Neville), 108
Jamaica : Earthquake on July 16, 186
Japan : Earthquake on September 10, 324
  Earthquake on Hokkaido Island on June 13, 353
Japanese : The (John F. Embree) (Smithsonian Institution War Background Studies, No. 7), 72
Jefferson (Thomas) as Natural Philosopher (Dr. Harlow Shapley), 178
Jewellers : Gem Testing for (B. W. Anderson), *review*, 6
Johne's Disease and Leprosy : Infection of Laboratory Animals with (John Francis), 250, 449 ; (C. C. Twort), 449
Jones-Bateman Cup of the Royal Horticultural Society : Conditions of the competition, 46
Joule (James Prescott) and the Unit of Energy (Prof. H. S. Allen), 354 ; (A. W. V. Mace), 418 ; (Graham Renshaw), 418 ; (J. H. Awbery), 479 ; (W. and R. Chambers, Ltd.), 479 ; (Prof. J. B. S. Haldane), 479 ; (Dr. K. R. Webb), 602 ; (Prof. C. H. Lees), 602 ; (Prof. W. Peddie), 602

KAMCHATKA Peninsula : Earthquake on August 10, 444
  (near the east coast of) Earthquake on March 7, 158
Kashmir : Archæological Excavation in, 701
  The Megaliths of Bursahom (Dr. Hellmut de Terra), 701
Kentucky Dam, Power House and Lock, 352
Kenya : A Miocene Anthropoid Mandible from Rusinga (Dr. L. S. B. Leakey), 319
  Training of Africans in the Meteorological Department, 212
α-Keratin : Structure of (Dr. Ian MacArthur), 38
Keratins Treated with Hot β-Naphthol Proteinases : Cleavability of (Dr. N. Lichtenstein), 249
Kew : Earthquakes registered during May, 45 ; during June, 353 ; during July, 624 ; during August, 624 ; during September, 720
Kilns suitable for Drying Indian Woods : Types of Timber Seasoning (M. A. Rehman), 242
Kinetics of Colloid Systems (Prof. S. S. Joshi), 618
Kingsholm, Gloucester : Origins of, 219
Knee Joint at Various Ages : Changes in the (Prof. Granville A. Bennett, Dr. Hans Waine and Prof. Walter Bauer), *review*, 35
Knowledge of Physical Objects (Dr. A. C. Ewing), 242
Knowledge of the Physical World : Our, 242

LABORATORY Animals with Johne's Disease and Leprosy : Infection of (John Francis), 250, 449 ; (C. C. Twort), 449
Laboratory Handbook of Pulp and Paper Manufacture (Dr. Julius Grant), *review* by Dr. V. G. W. Harrison, 8
Labour in the Building Industry (P E P Broadsheet No. 212), 562
Labour (Colonial) and Social Development (Prof. Daryll Forde), 203
Labour Conditions in Ceylon, Mauritius and Malaya (Major G. St. J. Orde Browne), 203

Labrador Rivers (Newfoundland and) : Obstructions in (A. A. Blair), 753
Lac : Control of the Insect Enemies of (P. S. Negi), 639
Lake Erie : Earthquake on March 9, 158
Lake Tanganyika : A Transverse Zoo-geographical Barrier on the East Side of (R. E. Moreau), 569
Lamps Burning : Keep the (Dr. van der Tempel), 312
Land : The Way of the (Sir George Stapledon), *review* by Dr. Hugh Nicol, 118
Land to Grass (Laying Down): The Clifton Park System of Farming and (Robert H. Elliot), fifth edition, *review*, 737
Land, Air and Ocean (R. P. Beckinsale), *review*, 399
Langstroth, the Apiarist, *review* by Dr. H. M. Fraser, 62
Language (International Auxiliary) : Otto Jespersen and an (H. Jacob), 324
Languages : International (E. T. Harris), 601
Laryngology and Folk-Lore (Dr. J. D. Rolleston), 212
Leadership in a Dynamic Society, 85
Leather, (Textile,) Shoe and Allied Trades : Rheology in the (British Rheologists' Club discussion on), 272, 514
Legendre Associated Functions : Tables of (Zaki Mursi), *review*, 399
Legumes (Cereals and) : Ascorbic Acid Content of Recently Harvested (M. N. Rudra), 78
Lemmings : Voles, Mice and (Charles Elton), *review* by M. A. C. Hinton, 395
Lepidoptera : Stereomorphism in Cryptic Coloration of (Dr. B. N. Schwanwitsch), 508
Leprosy (Johne's Disease and) : Infection of Laboratory Animals with (John Francis), 250, 449 ; (C. C. Twort), 449
Letters of Astronomical Interest : Some Old, 623
Levy Medal of the Franklin Institute awarded to Anders Henrik Bull, 45
Libraries (Special and General) : Functions of the (G. Woledge), 687
Library Service in Great Britain, 733
Library Stocks of Periodicals (Cyril C. Barnard), 106, 243
Liesegang Rings : Some Effects on (Dr. H. Friedeberg), 305
Life (Everyday) : Micro-Organisms in, *review*, by Dr. R. St. John-Brooks, 674
Life in the Primates (Social) : Relation between Body-size, Waking Activity Size of Eye-balls, and the Origin of (Prof. M. F. Ashley Montagu), 57
Lightning Protection of Buried Cable (E. D. Sunde), 424
Linacre Lecture for 1943 (Prof. Major Greenwood), 561
Lipæmogenic Activity of Pituitary Extracts (M. R. A. Chance and T. H. Middleton), 725
Literature (World's Non-Fiction) : A Plan for Mobilizing Bibliographical References to the Contents of the (Prof. A. F. C. Pollard), 541
Liversidge Lecture (Prof. S. Sugden), 754
Load Distribution between Interconnected Power Stations (Paul G. Kaufmann), 108
Local Expenditure : Standards of—a Problem of the Inequality of Incomes (Prof. J. R. Hicks and U. K. Hicks), 226
Local Government : Reconstruction of, 113
Local Rule : The British Way in (Guy Hunter), 226
Logic : A Modern Elementary (Prof. L. Susan Stebbing), *review* by Dr. S. V. Keeling, 706
Logical Empiricism, *review* by Prof. Herbert Dingle, 397
London (County of) Plan (J. H. Forshaw and Prof. Patrick Abercrombie), *review*, 227
Longevity of Paramecium (L. L. Woodruff), 419
Longevity (American) : Increase in, 443
Longstreth Medals of the Franklin Institute awarded (jointly) to Robert Griffin De La Mater and William Schwemlein, 45
Louvar : Osteology of the, 360
Low-Income Families : Needs of (D. Caradog Jones), 223
Lung : Physiology of the (Dr. O. A. Trowell), 153
Luvarus imperialis, a Scombroid Fish : The Osteology of (William K. Gregory and G. Miles Conrad), 360
Luxmoore Committee on Post-War Agricultural Education : Report of the, 165
Lychnis : Petal-Colour Inheritance in (H. G. Baker), 161
l-Lysine Decarboxylase—Preparation of Specific Enzyme and Coenzyme (Ernest F. Gale and Helen M. R. Epps), 327

MACQUARIE Islands (north east of) : Earthquake on September 6, 720
Madras Government Museum : Amaravati Sculptures in the (C. Sivaramamurti), *review* by E. J. Thomas, 87
Magnesium-Calcium Antagonism in Muscle (Dr. G. D. Greville and Dr. H. Lehmann), 81
Magnetochemistry (Prof. S. Sugden), 754
Magnitudes of Double Stars : Photovisual (A. W. J. Cousins), 512
Malaya (Ceylon, Mauritius and) : Labour Conditions in (Major G. St. J. Orde Browne), 203
Male Germ Cells of the Dog and Cat (Developing) : A Nuclear Ring in the (Prof. J. Bronte Gatenby), 79
Malignant Cell : A Speculation on the Nature of the Chemical Structure which is the Essence of the (H. Donovan and Dr. D. L. Woodhouse), 509
Malocclusion (Dental) in the Quintuplets (N. Ford and A. D. Mason), 361
Man : The Earth and (Prof. Darrell Haug Davis), *review*, 147
    Iron Excretion and Metabolism in (Dr. R. A. McCance and Dr. E. M. Widdowson), 326
    Microbiology and (Prof. Jorgen Birkeland), *review* by Dr. R. St. John-Brooks, 674
    Race, Class and Mating in the Evolution of (Dr. C. D. Darlington), 315
    Rh Genotypes in (R. R. Race, Dr. G. L. Taylor, Miss Kathleen E. Boorman and Miss Barbara E. Dodd), 563
Man (Adult) : Digestibility of Oatmeal Phytin by (E. W. H. Cruickshank, J. Duckworth, H. W. Kosterlitz and G. M. Warnock), 384
Man in Burma (Early) : Research on (M. C. Burkitt), 335
Mandible from Rusinga, Kenya : A Miocene Anthropoid (Dr. L. S. B. Leakey), 319
Manganese Deficiency in Oats (E. S. Twyman), 216
Manual Skill : Culture and (C. W. Hansel), 513
Map Projection : An Introduction to the Study of (Dr. James Mainwaring), *review* by A. Hinckley, 146
Map Projections by Practical Construction (A. Hinckley), *review*, 614
Mares' Serum Gonadotrophin : Purification of (Dr. C. Rimington and I. W. Rowlands), 355
Marine Biological Research and the South African Fishing Industry (Dr. Wm. Edwyn Isaac), 515
Marine Biology in the West Indies (Prof. C. M. Yonge), 136
Marine High-frequency Radio Unit (E. J. Girard), 657
Marine Organisms : Density of Certain (A. G. Lowndes), 511
Maternity : Arapesh (R. F. Fortune), 164
Mathematical Statistics : Russian Interest in, 185
Mathematical Tables and Aids to Computation, 352, 382
Mating in the Evolution of Man : Race, Class and (Dr. C. D. Darlington), 315
Mauritius, Fisheries of : Appointment of Dr. J. F. G. Wheeler as marine biologist, 408
Mauritius and Malaya (Ceylon,) : Labour Conditions in (Major G. St. J. Orde Browne), 203
Mayer Award for 1943 of the U.S. National Academy of Sciences, 720
Meals (Family) : Sociological Value of (Prof. J. H. S. Bossard), 271
Measurement of Anomalous Viscosity by the Capillary Tube Method (A. C. Merrington), 214
Mechanical Physics (Prof. Herbert Dingle), *review* by Dr. L. F. Richardson, 7
Mechanism of Polysaccharide Production from Sucrose (Shlomo Hestrin and Mrs. S. Avineri-Shapiro), 49
Mechanics (Fluid) and Statistical Methods in Engineering (Hugh L. Dryden, Theodore von Kármán, Anton A. Kalinske, Thomas K. Sherwood, Samuel S. Wilks, Walter A. Shewhart, Leslie E. Simon and Roscoe Pound), *review*, 119
Medals : Aeronautical, 532
Medical Investigations as Applicable to the Armed Forces (Royal Society of Canada symposium on), 362
Medical Research in War-time (Sir Edward Mellanby), 500
Medical Services (Public) : Organization of, 442
Medical Use of Sulphonamides (Medical Research Council War Memorandum No. 10), 561
Medicine : Absorption Spectra in, *review* by Dr. R. A. Morton, 342
    Authority in (Prof. Major Greenwood), 561
    Spectrophotometry in (Dr. Ludwig Heilmeyer), translated by Dr. A. Jordan and T. L. Tippell, *review* by Dr. R. A. Morton, 342
Medicine (Biology and) : Microscopic Technique in (Prof. E. V. Cowdry), *review* by Prof. R. C. McLean, 709
Medicines : Advertisement of Proprietary, 574
Mediterranean Culture (Sir John Myres), 534
Mediterranean Region : Plant Geography of the, *review* by Miss G. M. Roseveare, 117
Megaliths of Bursahom, Kashmir (Dr. Hellmut de Terra), 701
Megatectonics and Microtectonics (S. I. Tomkieff), 347
Melandrium : Sexuality in (D. Löve), 220
Membrane Equilibrium : The Donnan (S. G. Chaudhury), 76
'Memory' in a Carboy : Surface (Herman A. Liebhafsky and Lester B. Bronk), 695
Men : Mice and, *review* by M. A. C. Hinton, 395
Mercury : Slip and Twinning in Single Crystals of (A. Fisher), 567 ; (Prof. E. N. da C. Andrade), 567
    Solubility of Metals in (C. H. Prescott), 108
Metabolic Products of Moulds (Bacteriostatic) : A Suggestion respecting the (Sir Robert Robinson), 162
Metabolism in Man : Iron Excretion and (Dr. R. A. McCance and Dr. E. M. Widdowson), 326
Metabolism (Carbohydrate) : Vitamin C and (Sachchidananda Banerjee), 329
Metallic Films : Frictional Properties of (Dr. Robert Schnurmann), 247 ; (Dr. T. P. Hughes and J. L. Heaton), 247
Metallurgy (Spanish) since the National Movement (F. Millan), 755
Metals in Mercury : Solubility of (C. H. Prescott), 108
Metals (Alkali) : Alloys of Gold with (Dr. A. Sommer), 215
Metals (Cold-worked) : New X-Ray Evidence of the Nature of the Structural Changes in (Dr. H. Lipson and A. R. Stokes), 20
Meteor Data (British) : An Analysis of (J. G. Porter), 420
Meteorological Workers : African, 212
Meteorology as a Cultural Subject, *review* by Prof. D. Brunt, 585
Metre Waves : Radio Research on, 83
Mexico : Dedication of the new Seismograph at the National Astrophysical Observatory, Tonantzintla, 272
    Earthquake on February 22, 272
Mice and Men, *review* by M. A. C. Hinton, 395
Mice and Lemmings : Voles, (Charles Elton), *review* by M. A. C. Hinton, 395
Microanalysis of Organic Compounds : A New Technique for the Ultimate (Dr. F. B. Strauss), 446
Microbiological Assay of Riboflavin (Dr. Frank C. Happold), 414 ; (Dr. E. C. Barton-Wright and R. Gordon Booth), 414 ; (Prof. R. H. Hopkins), 724
Microbiological Degradation of Sterols, 332
Microbiological Methods in Vitamin Research : Historical Development of (Dr. Mary Sandford), 374
Microbiology of the Air, *review* by Prof. R. C. McLean, 258
Microbiology and Man (Prof. Jorgen Birkeland), *review* by Dr. R. St. John-Brooks, 674
Micro-Chemical Analysis (Micro-Chemical Club, the South Yorkshire Section of the Royal Institute of Chemistry and the Sheffield Metallurgical Association symposium on), 555
Micro-Chemical Analysis : Developments in (E. J. Vaughan), 555
Microchemical Apparatus (Stanley J. Davies), 80
Micro-Organisms in Everyday Life, *review* by Dr. R. St. John-Brooks, 674
Microphotometer : A Direct-Intensity, 753
Microscope : Beyond the (Kenneth M. Smith), *review*, 648
Microscope (Telescope,) and Barometer as a Point of Departure for the Natural Sciences (Prof. Louis C. Karpinski), 719
Microscopes : Reflecting (Dr. C. R. Burch), 748
Microscopic Technique in Biology and Medicine (Prof. E. V. Cowdry), *review* by Prof. R. C. McLean, 709
Microscopy in Ultra-Violet Rays : Colour (E. M. Brumberg), 357
Microtectonics : Megatectonics and (S. I. Tomkieff), 347
Middle East Supply Centre : Activities of the, 671
Milk : More and Better, 237
    The Production, Supply and Marketing of (J. L. Davies), 237
Milk Processing : The Bacteriological Aspects of (Dr. A. T. R. Mattick), 238
Milk Production of Dairy Cows by Feeding Thyroid-active Iodinated Proteins : Stimulation of the (K. L. Blaxter), 751
Milk and Milk Products : The Chemical Composition and Nutritive Value of (Dr. S. K. Kon), 238
Milk (Cow's) : Xanthine Oxidase Activity of (Alastair N. Worden), 505

Miller Medal of the Royal Society of Canada awarded to Prof. Norman Levi Bowen, 362
Minds: Other (7), (John Wisdom), 623
Mineral Control (International) : Problems of, 607
Mineral Deficiencies in Plants by Visual Symptoms : The Diagnosis of (Dr. T. Wallace), *review*, 709
Miners' Welfare Scholarships and Exhibitions : Award of, 298, 596
Mines : Electricity in (J. A. B. Horsley), 747
Miocene Anthropoid Mandible from Rusinga, Kenya (Dr. L. S. B. Leakey), 319
Mirrors before Aluminizing : Cleaning of (Vladimir Vand), 420
Mites in Stored Products : Tyroglyphid (M. E. Solomon), 632
Mitosis : Chemical Control of (Dr. P. T. Thomas and R. Drew), 564
  Probable Function of Histone as a Regulator of (Dr. E. Stedman and Mrs. Ellen Stedman), 556
Mittelmeerländer : Das Pflanzenkleid der (Prof. Dr. M. Rikli), Lief. I and Lief. 2, *review* by Miss G. M. Roseveare, 117
Moche and Virú Valleys, Peru (Chicama,) : Skeletal Remains from Cultural Associations from the (T. D. Stewart), 332
Modulation : Frequency (K. R. Sturley), *review*, 175
Molecular Constitution as Factors in Drug Action : Permeability and (Dr. H. Hurst), 292
Molecular Spectra and their Applications (Dr. Andrew McKellar), 362
Molecular Weight of Native Cellulose (Nils Gralén and Prof. The Svedberg,) 625
Molecules (Organic) : Fluorescence of (Dr. Joseph Weiss), 176
Mollusca of Australia : Basic List of the Freshwater (Tom Iredale), 696
Molluscs of Burma : Pleistocene (J. Bequaert), 335
Molucca Passage : Earthquake on September 5, 720
Mond Lecture (Sir Edward Mellanby), 500
Moon : Eclipse on August 15, 131
Morphology of the Algæ (Comparative) : Studies in the (3) (Prof. F. E. Fritsch), 632
Mortality : Infant, *review* by Prof. Lancelot Hogben, 460
Mosquitoes of the Americas : Sabethine (Dr. John Smart), 279
Mosquitoes in Portsmouth : Tank-breeding (John F. Marshall), 18
Moth *Sitotroga cerealella* Oliv. (Angoumois Grain) : The Development of the (Dr. A. C. Crombie), 246
Mother and Child : War-Time Food for (Dr. Geoffrey Bourne), *review*, 371
Moths Infesting Stored Food Products : Taxonomy of the (Dr. A. Steven Corbet), 742
Moths (Noctuid) at Light Traps in America (H. H. Walkden and D. B. Whelan), 24
Moths (Owlet) : The Trapping of (H. H. Walkden and D. B. Whelan), 24
Motion : Photographic Analysis of (E. R. Davies), 261
Moulds : A Suggestion respecting the Bacteriostatic Metabolic Products of (Sir Robert Robinson), 162
Moulds (Cellulose Acetate) : Recording Low Relief in Metallic Surfaces by (Capt. A. T. J. Dollar), 248
Mountains : Seismological Evidence for Roots of (Prof. Beno Gutenberg), 576
Mouse : The Genetics of the (Dr. Hans Grüneberg), *review* by Dr. C. H. Waddington, 585
Mouse (Field) : Tularæmia in the Shrew and the (Glen M. Kohls and Edward A. Steinhau), 632
Mouse Carcoma (Dibenzanthracene) : Long-term Cultivation *in vitro* of a (Dr. F. Jacoby), 299
Mouth-parts of Biting and Disease-carrying Flies (R. E. Snodgrass), 632
Mullet (Australian) : Studies in the Biology of, I : Account of the Fishery and Preliminary Statement of the Biology of *Mugil dobula* Gunther (G. L. Kesteven), 110
Mumbwa Caves, Northern Rhodesia : Further Excavations (1939) at the (J. Desmond Clark), 252
Muscle : Magnesium-Calcium Antagonism in (Dr. G. D. Greville and Dr. H. Lehmann), 81
Muscle and Isolated Strips of Myosin (Isolated) : Relation between Experiments on (Major Inderiit Singh), 132
Muscular Dystrophy (Progressive) : On Pseudohypertrophic and Allied Types of (Julia Bell), *review* by Dr. F. W. Sansome, 260
Museum Objects in War-Time : Preservation of (Dr. H. J. Plenderleith) 94
Museums in Italy : Preservation of, 472
Museums and the Public, 320
Mutation of *Drosophila pseudo-obscura* : High Rate of (K. Mampell), 696
Mutation and the Rhesus Reaction (Prof. Lancelot Hogben), 721
Mycelium of *Polystictus hirsutum* Fr. (Binucleate) : Binucleate Oidia on (S. R. Bose), 508
Mycology (Industrial) : An Introduction to (George Smith), second edition, *review* by Dr. J. Grainger, 173
Mystacocarida, a New Order of Crustacea from Intertidal Beaches in Massachusetts and Connecticut (Robert W. Pennak and Donald J. Zinn), 167
Myers Memorial Lecture for 1942 (G. N. M. Tyrrell on Apparitions), *review*, 119
Myosin (Isolated Strips of) : Relation between Experiments on Isolated Muscle and (Major Inderjit Singh), 132

NAILS (Bamboo), their Manufacture and Holding Power (V. D. Limaye), 756
Naivasha Fossil Skull and Skeleton (Dr. L. S. B. Leakey and Mrs. Leakey), 511
β-Napthol by Proteinases (Hot) : Cleavability of Keratins Treated with (Dr. N. Lichtenstein), 249
Narcotic Drug Addicts (Dr. Michael J. Pescor), 297
National Administrative Staff College, 100, 472
National Defence Scientific Problems : Cash awards for solutions of (Council for the Promotion of Science and Technology in China), 534
National Expenditure, Select Committee on : Tenth report, 270 ; Fifteenth Report, 688
Nationality : Science and, 253
Native Peoples of New Guinea (M. W. Stirling), 166
'Natural' and 'Supernatural' (G. N. M. Tyrrell), 325
Naturalists : American Army, *review*, 61
Nectrioideæ and Allied Genera : British (T. Petch), 633
Needs of Low-Income Families (D. Caradog Jones), 223
Nervous Excitation : Role of Acetylcholine and Vitamin B_1 in (Prof. A. v. Muralt), 188
Nervous System : Nutrition in relation to Bone Growth and the (Sir Edward Mellanby), 111
Neutralization in Insulating Papers : Acid (D. A. McLean), 140
Neutrons (Fast) : Treatment of Cancer by (Dr. L. H. Gray and Dr. J. Read), 53
New Guinea : Earthquake on March 21, 101
  The Island of (Miss L. Evelyn Cheesman), 41
  Native Peoples of (M. W. Stirling), 166
  Peoples of (Mrs. K. Rishbeth), 166
New Guinea (Modern) : The Making of (Stephen Winsor Reed), *review* by Miss L. Evelyn Cheesman, 6
New World Archæological Finds : A Synthesis of, 577
New York : District Heating in, 500
New Zealand : Earthquakes registered during 1941, 111 ; during February 18 ; during March, 74 ; during April, 213 ; during July, 624
  Health of, 158
New Zealand Department of Scientific and Industrial Research : Seventeenth Annual Report, 603
New Zealand Region from Seismic Data : The Subcrustal Structure in the (R. C. Hayes), 512
Newfoundland and Labrador Rivers : Obstructions in (A. A. Blair), 753
Newspaper : The (Ivor Thomas), 193
Newt Larvæ in Brackish Water (Frederick Burke and E. G. Williams), 566
Newton, : El Tricentenario de (Mario Bunge), 719
Nickel Oxide : Structure of (H. P. Rooksby), 304
Nicotinamide (F_2 of Najjar and Collaborators) : Urinary Elimination Products following Ingestion of (Dr. P. Ellinger and R. A. Coulson), 383
Nineteenth Century : Some Czechoslovak Contributions to Chemistry in the (Dr. Gerald Druce), 239
Nineteenth Century Buns and Ale : Riboflavin and Vitamin B_1 in (Dr. E. C. Barton-Wright, Dr. T. Moran and H. S. Sarson), 273
Nitric Oxide : Oxidation of (J. H. Smith), 333
Nitrogen between the Take-all Fungus and the Roots of Crop Plants : Competition for (S. D. Garrett), 417
Noctuid Moths at Light Traps in America (H.H. Walkden and D. B. Whelan), 24
Norway Rat : Degree of Tameness of Varieties of the (C. E. Keeler), 107
Notation of Jacobian Elliptic Functions (Prof. E. H. Neville), 108
Nova Aquilæ, 444
Nuclear Disintegration in a Wilson Chamber : Photograph of a (M. Sinha), 568
Nuclear Ring in the Developing Male Germ Cells of the Dog and Cat (Prof. J. Bronte Gatenby), 79
Nucleic Acid in the Cell : Distribution of (H. G. Callan), 503 ; (Dr. Edgar Stedman and Dr. Ellen Stedman), 503
Nucleic Acids : Terminology of (Dr. A. W. Pollister and Dr. A. E. Mirsky), 692
Nucleotides and Nucleosides (Relation of) to Proliferation-Promoting Factors produced by Ultra-Violet Irradiated Yeast Cells (Prof. Elton S. Cook, Sr. Ann Gertrude Cronin, Cornelius W. Kreke and Sr. Thomas Mary Walsh), 474
Nutrition in relation to Bone Growth and the Nervous System (Sir Edward Mellanby), 111
Nutritional Relief : Post-War (Nutrition Society conference on), 444, 615
Nutritional Research in the Crown Colonies (D. Fitzgerald Moore), 418
Nutritive Value of Milk and Milk Products : The Chemical Composition and (Dr. S. K. Kon), 238

OATMEAL Phytin by Adult Man : Digestibility of (E. W. H. Cruickshank, J. Duckworth, H. W. Kosterlitz and G. M. Warnock), 384
Oats : Manganese Deficiency in (E. S. Twyman), 216
Occultation of Venus (M. A. Ellison), 18
Ocean : Chemical Evolution of the (Prof. E. J. Conway), 511
  Land, Air and (R. P. Beckinsale), *review*, 399
Ocular Muscles and Vision (Dr. F. W. Edridge-Green), 331
Oidia (Binucleate) on Binucleate Mycelium of *Polystictus hirsutum* Fr. (S. R. Bose), 508
Ointment Boxes (Pill and) : Bamboo (Sultan Mohammed), 757
Onion Plants Grown from Sets : Bulb Formation and Flower Production in (O. V. S. Heath and M. Holdsworth), 334
Operational Calculus (Prof. H. T. H. Piaggio), 93
Ophthalmological Research at Oxford, 323
Optical Instruments : Principles of the Use of Non-Reflecting Films in (Dr. K. M. Greenland), 290
Optical Methods of Chemical Analysis (Dr. Thomas R. P. Gibb, Jr.), *review* by Dr. R. A. Morton, 552
Optical Topics in part connected with Charles Parsons (Lord Rayleigh), 46, 410, 676
Optically Active Selenonium Salt (Dr. F. G. Mann and F. G. Holliman), 749
Optics, the Technique of Definition (Arthur Cox), *review*, 90
Optics in Research (Physical) : The Role of (Prof. J. K. Robertson), 362
Optics of X-Ray Analysis : Physical (Sir Lawrence Bragg), 542
Oranges : Vitamin C Content of (Dr. Arthur D. Holmes, James A. Patch and Francis Tripp), 74
Ore Deposits as related to Structural Features (edited by W. H. Newhouse), *review* by Prof. J. A. S. Ritson, 432
Organic Compounds : A New Technique for the Ultimate Microanalysis of (Dr. F. B. Strauss), 446
  Dictionary of (Prof. I. M. Heilbron and H. M. Bunbury), Vol. I : Abietic Acid—Dypnone, new, revised and enlarged edition, *review* by Prof. John Read, 586
Organisms (Certain Marine) : Density of (A. G. Lowndes), 511
Organization (International) : Functional Development of, 309
Origin Myth of the Acoma Pueblo Indians (M. W. Stirling), 24
Origin of Social Life in the Primates : Relation between Body-size, Waking Activity, Size of Eye-balls, and the (Prof. M. F. Ashley Montagu), 573
Origins of Kingsholm, Gloucester, 219
Ornithologists of the United States Army Medical Corps (Colonel Edgar Erskine Hume), *review*, 61
Oscillator Control : High Crystal Harmonics for (I. E. Fair), 363
Oscillographic Method for the Determination of the Velocity of Sound (J. M. A. Lenihan), 661
Osmotic Regulation in *Sabella pavonina* (Dr. D. W. Ewer and R. F. Ewer), 598

Osteology of *Luvarus imperialis*, a Scombroid Fish (William G. Gregory and G. Miles Conrad), 360
Oterma 1943*a*, Comet : Orbit for, 444
Owlet Moths : The Trapping of (H. H. Walkden and D. B. Whelan), 24
Oxford : Ophthalmological Research at, 323
Oysters of the Western Atlantic (Richard A. McLean), 419

PACIFIC Ocean : Earthquakes on March 15 and 21, 101 ; on June 15, 353
  (west of California) : Earthquake on September 10, 720
  (off the south-west coast of Guatemala) : Earthquake on August 31, 624
  (near the east coast of Kamchatka) : Earthquake on March 7, 158
  (west of the Marianas Islands) : Earthquake on April 9, 213
  (west of Mexico) : Earthquake on September 20, 720
  (between Samoa and the Friendly Islands) : Earthquake on September 11, 720
Packing Cases : Testing of and Improvement in Design of (V. D. Limaye), 242
Paguridæ and Cœnobitidæ (Dr. E. F. Thompson), 363
Painting : The Psychology of Cultural Change in (Dr. R. W. Pickford), *review* by F. Ian G. Rawlins, 31
Paints (Ships' Antifouling) : Research and (Dr. P. Ewart Bowles), 159 ; (Dr. G. D. Bengough), 159
Palestine : Production of Freshwater Fish in (C. K. Ricardo Bertram), 415
  Typhus in, 658
Paper Manufacture (Pulp and) : A Laboratory Handbook of (Dr. Julius Grant), *review* by Dr. V. G. W. Harrison, 8
Papers (Insulating) : Acid Neutralization in (D. A. McLean), 140
Papuan Children : Mid-dorsal Hair Whorls in (Dr. Frank Fenner), 538
'Paracon', a new speciality Rubber (Bell Laboratories), 297
Paramecium : Longevity of (L. L. Woodruff), 419
Paraffin Wax by Bacteria : Breakdown of—a Source of Error in Corrosion Tests (T. Howard Rogers), 105
Paramecium : Influence of Colchicine Alone and Combined with X-Rays on (L. Halberstaedter and A. Back), 275
Paranthropus robustus : An Ankle-Bone of the Ape-Man (Dr. R. Broom), 689
Parasite of Freshwater Fish (a Ciliate Protozoan) : Observations on Some Phases of the Life Cycle of *Ichthyophthirius multifiliis* Fouquet 1876 (A. Dunbavin Butcher), 753
Parasitological Research in Free China (K. Chang), 699
Parasitology in Free China (Dr. G. Lapage), 699
Paroxysmal Tachycardia : Etiology of (Dr. Richard F. Öhnell), 216
Parsons Memorial Lecture for 1943 (Lord Rayleigh), 46, 410, 676
Patent Medicines (Mass Observation), 574
Pattern of Youth, an Interim Report (Dr. R. E. G. Armattoe), 217
Pattern (Repeating) : Binocular Focusing on a (Nellie Henderson), 726
Patterson Diagrams : Interpretation of (Prof. J. Monteath Robertson), 411
Patulin, 619
Patulin : An Antibacterial Substance from *Aspergillus clavatus* and *Penicillium claviforme* and its Probable Identity with (Dr. F. Bergel, A. L. Morrison, A. R. Moss, R. Klein, H. Rinderknecht and J. L. Ward), 750
Peace : The Challenge of, 281
  Food and the Strategy of, 1
  The Transition from War to (A. C. Pigou), 193
  Can We Win the (Paul Einzig), 172
Peace and the Threefold Commonwealth (T. G. Jones), 351
Peace System : A Working (Prof. D. Mitrany), 311
Peace (War and) : Substitute Materials in (Dr. C. H. Desch), 184
Peace (War to) : The Transition from, Part I (League of Nations Report of the Delegation on Economic Depressions), 365
Peace (World) : Anglo-American Unity and, 296
Peace-time : Radiolocation and Shipping Risks in, 688
Pears (Fertility and Conference) : Seedless Fruits of (M. B. Crane, A. G. Brown and D. Lewis), 24
Pectin : A New Source of (T. P. Ghose and S. Krishna), 24
Pedigrees of Polydactylism (J. M. Odiorne), 360
Pelagic Tunicates in the Plankton of South-eastern Australian Waters and their Place in Oceanographic Studies (Dr. Harold Thompson), 110
Pellia epiphylla : How the Sperm reaches the Archegonium in (Prof. John Walton), 51
Penatin (W. Kocholaty), 604
Penicillin : Dominion Government of Canada to establish plants and equipment for the production of, 502
  Inhibition of Urease by (Lt.-Col. Joseph C. Turner, Capt. Frederick K. Heath and Boris Magasanik), 326
  Progress with, 605
  Researches on, 604
  (Royal Society of Medicine discussion on), 619
  Synergistic Effect of Para-aminobenzoic Acid and Sulphapyridine on (Dr. J. Ungar), 245
Penicillin in America, 604
Penicillin in the U.S.A., 605
Penicillin and other Antibiotic Substances : Abstracts on (compiled by Miss Muriel E. Whalley), 747
Penicillin Assay : A New Rapid Method for (Ursula Wilson), 475
Penicillin-like Substance from *Aspergillus giganteus* Wehm. (Mrs. Flora J. Philpot), 725
Penicillium claviforme and its Probable Identity with Patulin : An Antibacterial Substance from *Aspergillus clavatus* and (Dr. F. Bergel, A. L. Morrison, A. R. Moss, R. Klein, H. Rinderknecht and J. L. Ward), 750
Peoples of the East Indies : Islands and (Raymond Kennedy), 688
Peoples of New Guinea (Mrs. K. Rishbeth), 166
Peoples of New Guinea : Native (M. W. Stirling), 166
People's Homes : An Enquiry into (Mass-Observation Report), *review* by Lieut. T. H. Hawkins, 257
Perianth (Trimerous) : Origin of the (Prof. A. C. Joshi), 695
Periodic System : Radioactivity and the Completion of the (Dr. Leo Ponisovsky), 187
Periodicals : Library Stocks of (Cyril C. Barnard), 106 ; 243
  The Subject Index to, 1941 (Library Association), *review*, 90
Permeability and Molecular Constitution as Factors in Drug Action (Dr. H. Hurst), 292
Perovskite Type of Structure : Silicates of the (H. J. Goldschmidt and J. R. Tait), 356
Peru : Earthquake on June 30, 410
  (off the coast of) : Earthquake on July 5, 410
  Public Health in (Dr. Manuel Prado), 297
  Skeletal Remains from Cultural Associations from the Chica, Moche and Virú Valleys (T. D. Stewart), 332
Pests of Stored Products (Three Insect) : Diurnal Activity of (Dr. R. F. Ewer), 133
Pests of the Potato : Soil (G. Fox Wilson), 633
Petal-Colour Inheritance in Lychnis (H. G. Baker), 161
Petrie's (Flinders) Racial Types (Dr. O. J. R. Howarth), 510
Petrology of Igneous Rocks, *review* by Dr. G. W. Tyrrell, 433
Petunia : Pollen Tetrads in (H. Levan), 219
*p*F Scale of Soil Moisture for Expressing the Soil Moisture Relations of Wire-worms : Value of the (A. C. Evans), 21
Pflanzenkleid der Mittelmeerländer (Prof. Dr. M. Rikli), Lief. 1 and Lief. 2, *review* by Miss G. M. Roseveare, 117
Phæophyceæ : The, 632
Pharmaceutical Codex (British) : Fifth Supplement, 186
Philosophy : Between Physics and (Philipp Frank), *review* by Prof. Herbert Dingle, 397
Philosophy (Physics and) : The New Algebras and their Significance for (Prof. E. T. Whittaker), 603
Phœnix and Samoan Islands : Fishes from the (Leonard P. Schultz), 511
Photographic Analysis of Motion (E. R. Davies), 261
Photographic Observations of Comets at Riverview College Observatory (D. J. K. O'Connell), 697
Photographic Survey of Galactic Clusters (George Alter), 220
Photography as an Aid to Scientific Work (Ilford, Ltd.), 74
Photography of Stars in Daylight (M. Waldmeier), 158
Photography : Clinical (Association for Scientific Photography meeting on), 298, 423
Photoreceptors : Vertebrate (Prof. Samuel R. Detwiler), *review* by Dr. Katharine Tansley, 61
Photovisual Magnitudes of Double Stars (A. W. J. Cousins), 512
Phthalic Acid : Alleged Vitamin K Activity of (Dr. Henrik Dam), 355
Phycomycetes : Aquatic, exclusive of the Saprolegniaceæ and Pythium (Frederick K. Sparrow, Jr.), *review* by Dr. B. Barnes, 462
Physical Growth : Factorial Analysis of (Prof. Cyril Burt), 75
Physical Objects : Knowledge of (Dr. A. C. Ewing), 242
Physical Optics in Research : The Role of (Prof. J. K. Robertson), 362
Physical Optics of X-ray Analysis (Sir Lawrence Bragg), 542
Physical Postulates : Proposals for New Basic (Dr. H. T. Townsend), 308
Physical Science (Applied) : B.B.C. Broadcasts on, 325
Physical World : Our Knowledge of the, 242
Physics : Analytical Experimental (Prof. Harvey Brace Lemon and Prof. Michael Ference, Jr.), *review* by Dr. Lewis F. Richardson, 432
  Introduction to Chemical (Prof. J. C. Slater), *review* by Sir Ralph Fowler, 488 ; *erratum*, 562
  Mechanical (Prof. Herbert Dingle), *review* by Dr. L. F. Richardson, 7
  Practical (Prof. March W. White, Dr. Kenneth V. Manning, Prof. Robert L. Weber, Dr. R. Orin Cornett and others), *review* by Dr. L. F. Richardson, 491
  School (T. M. Yarwood), Part I, *review*, 260
  Sub-Atomic (Prof. Herbert Dingle), *review* by Dr. L. F. Richardson, 7
  University (Dr. F. C. Champion), Part 5 : Electricity and Magnetism, *review* by Dr. L. F. Richardson, 7
Physics and Philosophy : Between (Philipp Frank), *review* by Prof. Herbert Dingle, 397
  The New Algebras and their Significance for (Prof. E. T. Whittaker), 603
Physiological Basis of Camouflage, 605
Physiological Regulations (Prof. Edward F. Adolph), *review* by Dr. O. A. Trowell, 735
Physiologically Active Fractions of Indian Hemp (B. C. Bose and Dr. B. Mukerji), 109
Physiology : Human (Kenneth Walker), *review*, 648
Physiology of Colour Vision (A. H. S. Holbourn), 190 ; (Prof. H. Hartridge), 190 ; (E. N. Willmer), 190
Physiology of the Lung (Dr. O. A. Trowell), 153
Phytin by Adult Man (Oatmeal) : Digestibility of (E. W. H. Cruickshank, J. Duckworth, H. W. Kosterlitz and G. M. Warnock), 384
Pickwick Basin : An Archæological Survey of (W. S. Webb, D. L. Dejarnette and others), 360
Pigeons (Wood) : Diet of, 533
Pigments (Blood) and Related Substances, 714
Pigments : The Tetrapyrrolic (Biochemical Society discussion on), 714
Pigs : Value of Horse Chestnuts as Food for (R. Braude), 571
Pill and Ointment Boxes : Bamboo (Sultan Mohammed), 757
Pituitary Extracts : Lipæmogenic Activity of (M. R. A. Chance and T. H. Middleton), 725
Pituitary Gland : Protein Hormones of the, 360
Place-Names of Cambridgeshire and the Isle of Ely (P. H. Reaney), *review* by M. C. Burkitt, 145
Plan for Reconstruction, a Project for Victory in War and Peace (Prof. W. W. Hutt), 86
Plane Tree (Alexander L. Howard), 421
Planetary System : Evolution of the (Lieut.-Colonel K. E. Edgeworth), 251
Planetary Systems : Non-Solar (H. K. Sen), 600 ; (Sir James Jeans), 721
Planets : Non-Solar (Dr. A. Hunter), 66
Planets and the Origin of the Solar System : Non-Solar (Dr. H. Alfvén), 721
Planisphere : The Pocket (Francis Chichester), *review*, 63
Plankton of Southeastern Australian Waters and their Place in Oceanographic Studies : Pelagic Tunicates in the (Dr. Harold Thompson), 110
Planning : Prolegomena to, *review* by D. J. Morgan, 256
  Research and, 141 ; (Prof. M. Polanyi), 217
Plant Analysis : Soil and (Dr. C. S. Piper), *review*, 370
Plant Diseases, 425
Plant Geography of the Mediterranean Region, *review* by Miss G. M. Roseveare, 117
Plant Geography (Historical) : An Introduction to (E. V. Wulff), authorized translation by Elizabeth Brissenden, *review* by Dr. H. Godwin, 490
Plant Geography : Polyploidy and (A. and D. Löve), 219
Plant Physiology : Role of Vitamins in, *review* by Dr. R. D. Preston, 706
Plant Pot : Soil Conditions in the (A. G. Pollard and C. W. R. Smith), 419
Plants : The Carnivorous (Dr. Francis Ernest Lloyd), *review*, 63

Plants by Visual Symptoms : The Diagnosis of Mineral Deficiencies in (Dr. T. Wallace), *review*, 709
Plants and Vitamins (W. H. Schopfer), *review* by Dr. R. D. Preston, 707
Plastics (Allied) : Synthetic Resins and (edited by Dr. R. S. Morrell), second edition, *review*, 398
Pleistocene Molluscs of Burma (J. Bequaert), 335
Pleistocene Period in Burma (Hellmut de Terra), 335
Pleistocene Vertebrates of Burma (Edwin H. Colbert), 335
Plough : Rotation and the, *review* by Dr. Hugh Nicol, 118
Plums : Pollination of (M. B. Crane and A. G. Brown), 24
Plywood : The Coming of, 651
Poliomyelitis in the Argentine, 297
Poliomyelitis in the United States, 688
Poliomyelitis (Human) in the Developing Chick Embryo (Sven Gard), 660
Polish Science and Learning, 409
Political Economy of Population (Prof. Radhakamal Mukerjee), *review* by Prof. H. J. Fleure, 60
Pollen Tetrads in Petunia (H. Levan), 219
Pollination of Plums (M. B. Crane and A. G. Brown), 24
Polydactylism : Pedigrees of (J. M. Odiorne), 360
Polymerization of Hydrogen and Deuterium Fluorides (R. W. Long, J. H. Hildebrand and W. E. Morrell), 420
Polymorphism of Arsenious Oxide (J. H. Schulman and W. C. Schumb), 754
Polyploidy in the Red Algæ (Miss Drew), 696
Polyploidy in the Potato (Prof. R. Ruggles Gates), 416
Polyploidy and Plant Geography (A. and D. Löve), 219
Polyploidy and X-Ray Dosage (K. Fröier, A. Gustafsson and O. Tedin), 419
Polysaccharide from Perennial Rye Grass Pasture : A New Water-Soluble (R. J. McIlroy), 724
Polysaccharide Production from Sucrose : Mechanism of (Shlomo Hestrin and Mrs. S. Avineri-Shapiro), 49
1, 3 Polysaccharides : Regulated Degradation of (Dr. Vincent C. Barry), 537
Polystictus hirsutum Fr. : Binucleate Oidia on Binucleate Mycelium of (S. R. Bose), 508
Poorer ? : Will the War Make Us (M. Young and Sir Henry Bunbury), 157
Population : The Political Economy of (Prof. Radhakamal Mukerjee), *review* by Prof. H. J. Fleure, 60
Population of a Seaport (Exhibit by the National Museum of Wales), 656
Population and Emigration, *review* by Prof. H. J. Fleure, 60
Pore Canals of the Insect Cuticle (R. Dennell), 50
Porto Rico (off the north-west coast of) : Earthquake on September 10, 720
Portsmouth : Tank-breeding Mosquitoes in (John F. Marshall), 18
Portugal : Earth Tremors on June 22, 74
Portugal e a Grã-Bretanha : Relaçoes cientificas entre (Prof. H. Amorin Ferreira), 61
Post-War Agricultural Education : Report of the Luxmoore Committee on, 165
Post-War Britain : Blue-Prints for, *review* by G. D. H. Cole, 312
Post-War Building Policy, 443
Post-War Demobilization of Scientific and other Personnel (Committee of Inquiry appointed by the Minister of Labour and National Service), 100
Post-War Economy of Britain (War and) : Coal Carbonization and the (E. V. Evans), 100
Post-War Employment (E. S. Conway), 642
Post-War Europe : Food and Farming in (P. Lamartine Yates and D. Warriner), *review*, 399
Post-War Forest Policy in Great Britain, 337
Post-War Nutritional Relief (Nutrition Society conference on), 444, 615
Post-War Relief in Europe, 634
Post-War Integration of Research Activities in the United States : War and (Dr. R. H. Heindel), 212
Post-War Needs of Universities in Great Britain, 595
Post-War World : Contribution of Archæology to the (Dr. Grahame Clark), 320
Post-War World Education (Dr. Grahame Clark), 500
Pot (Plant) : Soil Conditions in the (A. G. Pollard and C. W. R. Smith), 419
Potassium : Dual Decay of (Dr. F. C. Thompson and Dr. S. Rowlands), 103
Potato : Polyploidy in the (Prof. R. Ruggles Gates), 416
    Soil Pests of the (G. Fox Wilson), 633
Potato Eyes as readily transportable 'Seed' for the Colonies (Sir Geoffrey Evans), 464
Potato Seed Tubers from Stems : Propagation of (Dr. G. H. Bates), 135
Potato Strain of the Eelworm *Heterodera schachtii* Schmidt : A Modification of the Gemmell Single Cyst Technique for the (Dr. C. Ellenby), 133
Potato Tubers : Sprouting of (Dr. Maurice Copisarow), 275
Potatoes : Propagation of (Dr. L. G. G. Warne), 450 ; (Dr. Nicholas Polunin), 601
    Spore-forming Bacteria in (Dr. W. J. Dowson), 331
    Nature of Tetraploidy in Cultivated European (C. H. Cadman), 103
Potency (Relative) of Carcinogenic Hydrocarbons (Dr. W. R. Bryan and Dr. M. B. Shimkin), 360
Potts Medals of the Franklin Institute awarded to Dr. Don Francisco Ballen and to Dr. Paul R. Heyl, 45
Poultry : Feeding Horse Chestnuts and Elderberries to (H. Temperton), 345
Poverty and Health : Birth, (Richard M. Titmuss), *review* by Prof. Lancelot Hogben, 460
Poverty and Progress in China (P E P Broadsheet No. 209), 380
Power Stations (Interconnected) : Load Distribution between (Paul G. Kaufmann), 108
Precipitin Test for Typhoid Fever (Lt.-Col. S. S. Bhatnagar), 448
Predictions ? : Do all Statements make, 623
Prehistory of the Deccan (Maharashtra) : Studies in (H. D. Sankalia), 746
Preservation of Museum Objects in War-Time (Dr. H. J. Plenderleith), 94
Preservation of Museums in Italy, 472
Price Lecture (Sir Henry Dale), 500, 605
Primates : Relation between Body-size, Waking Activity, Size of Eye-balls and the Origin of Social Life in the (Prof. M. F. Ashley Montagu), 573
Products (Stored) : Diurnal Activity of Three Insect Pests of (Dr. R. F. Ewer), 133
    Tyroglyphid Mites in (M. E. Solomon), 632
Products (Stored Food) : Common Insect Pests of (Dr. H. E. Hinton and Dr. A. Steven Corbet), 272
Progress : The Long Road of (Dr. E. F. Armstrong), 687
Progress in China : Poverty and (P E P Broadsheet No. 209), 380
Proliferation-Promoting Factors produced by Ultra-Violet Irradiated Yeast Cells : Relation of Nucleotides and Nucleosides to (Prof. Elton S. Cook, Sr. Ann Gertrude Cronin, Cornelius W. Kreke and Sr. Thomas Mary Walsh), 474
Properties of Metallic Films : Frictional (Dr. Robert Schnurmann), 247 ; (Dr. T. P. Hughes and J. L. Heaton), 247
Properties of Stannous Sulphide : Semi-conducting (Merial C. Clark and J. S. Anderson), 75
Proprietary Medicines : Advertisement of, 574
Protective Finishes for Scientific Apparatus, 272
Protein Hormones of the Pituitary Gland, 360
Proteinases : Cleavability of Keratins Treated with Hot β-Naphthol by (Dr. N. Lichtenstein), 249
Proteins : A Neglected Constituent of—α-Amino-n-butyric Acid (Dr. Walter C. Tobie), 249
    Tuberculin (F. B. Siebert and J. W. Nelson), 25
Proteins (Thyroid-active Iodinated) : Stimulation of the Milk Production of Dairy Cows by Feeding (K. L. Blaxter), 751
Psycho-Analytical Vocabulary : A New German-English (Alix Strachey) *review* by Prof. J. C. Flugel, 492
Psychology : Dynamics in (Wolfgang Koehler), *review* by A. W. Wolters, 172
Psychology of Cultural Change in Painting (Dr. R. W. Pickford), review by F. Ian G. Rawlins, 31
Psychology (Industrial) : An Introduction to (Dr. May Smith), *review* by Dr. Millais Culpin, 230
Pterygota (Insecta) into Subordinate Groups : Subdivision of (Dr. B. N. Schwanwitsch), 727
Public : Museums and the, 320
Public Health : in Honduras (Dr. P. H. Ordónez Dias), 101
    in Peru (Dr. Manuel Prado), 297
    in Uruguay (Dr. J. C. Mussio Fournier), 352
Public Health Measures : Recent Advances in, 561
Public Health Services : Report on the Reform of (Sir Arthur McNalty), 442
Public Library Service, its Post-War Reorganization and Development (Library Association), 733
Public Medical Services : Organization of, 442
Public Opinion Research : The Limitation of Statistics in the Field of (J. G. Ferraby), 44
Pueblo Indian : The Life-History of a, *review* by Mrs. K. Rishbeth, 34
Pueblo Indians (Acoma) : Origin Myth of the (E. W. Stirling), 24
Pulp and Paper Manufacture : A Laboratory Handbook of (Dr. Julius Grant), *review* by Dr. V. G. W. Harrison, 8
Pyrethrin Concentrates during Storage : Products Formed in (Dr. T. F. West), 660

QUATERNIONS (Hamilton's) : The Significance and Development of (Prof. H. T. H. Piaggio), 553
    Issue of special postage stamps by the Government of Eire in celebration of, 553
    Royal Irish Academy Meeting in celebration of, 688
Quintuplets : Dental Malocclusion in the (N. Ford and A. D. Mason), 361

RABBIT Spermatozoa *in vitro* : X-Irradiation of (E. C. Amoroso and Dr. A. S. Parkes), 244
Rabbits and Guinea Pigs : Water Requirements of (Prof. E. L. Kennaway), 157
Race, Class and Mating in the Evolution of Man (Dr. C. D. Darlington), 315
Racial Types : Flinders Petrie's (Dr. O. J. R. Howarth), 510
'Radar', 391
Radio Detection and Ranging, 391
Radio Design : The Technique of (Dr. E. E. Zepler), *review*, 399
Radio Fade-Out on February 10, 1943 (Dr. A. Ogg), 664
Radio Goes to War (Charles J. Rolo), *review* by Dr. L. E. C. Hughes, 175
Radio Research on Metre Waves, 83
Radio Unit : Marine High-Frequency (E. J. Girard), 657
Radioactive Data : Variations in (N. B. and A. R. Keevil, W. N. Ingham and G. P. Crombie), 633
Radioactivity and the Completion of the Periodic System (Dr. Leo Ponisovsky), 187
Radio-Frequency Energy : Dehydration of Food by (Vernon W. Sherman), 560
Radiolocation and Shipping Risks in Peacetime, 688
Radium (X-Rays and) : Protection from (British X-Ray and Radium Protection Committee), 73
Radon to Trace the Flow Pattern of Gases in Furnaces : Use of (R. Mayorcas and M. W. Thring), 723
Rat (Norway) : Degree of Tameness of Varieties of the (C. E. Keeler), 107
Rations and Food Consumption in Sweden during 1942–43 (Carin Boalt and Yngve Zotterman), 635
Rats : Trypan Blue and Cell Migration in the Adrenal Cortex of (Italo Calma and Charles L. Foster), 536
Rays (Ultra-Violet and Daylight) : Variations of (Dr. J. R. Ashworth), 330
Reaction for Ascorbic Acid : A Specific (Dr. L. F. Levy), 693
Reactions : Hydrogen Exchange (H. V. A. Briscoe and co-workers), 757
Reader Over Your Shoulder (Robert Graves and Alan Hodge), *review* by Dr. E. H. Tripp, 645
Reconstruction : Anthropology in (Prof. F. C. Bartlett), 596, 710
    Economic (J. R. Bellerby), Vol. I, *review* by G. D. H. Cole, 312
    Educational, 120 ; (General Review), 393 ; (2), 427 ; (3) The Needs of Youth, 455 ; (4) Adult Education, 483 ; (5), 517 ; (6) Science as an Educational Discipline, 545 ; in England 169 ; Inter-Allied Bureau for, 444
    Plan for (Prof. W. W. Hutt), 86
    A Programme for, 744
    Research and the Universities in, 641
Reconstruction in Britain : Economics of, 157
Reconstruction in Great Britain : A Minister of, 594
    Plans for, 225
Reconstruction in Central Europe : Economic and Technical (F. Nemec), 621
Reconstruction of Local Government, 113

Reconstruction of the Social Order, 351
Red Blood Corpuscles : Colour of (Dr. John R. Baker), 331 ; (E. J. Bowen), 476 ; (D. A. Webb), 476 ; (Prof. H. Hartridge), 629
Redbrick University (Bruce Truscot), 549
Reductone and Vitamin C (Dr. J. G. A. Griffiths), 163
Rehabilitation of the 'Scorched Earth' in the U.S.S.R., 424
Relapsing Fever and B. *proteus X Kingsbury* (Major R. Elsdon-Dew), 565
Relief in Europe : Post-War, 634
Relief in Europe after the War of 1914–18, 194
Relief in Metallic Surfaces by Cellulose Acetate Moulds : Recording Low (Capt. A. T. J. Dollar), 248
Relief Deliveries and Relief Loans, 1919–23 (League of Nations), 194
Religion and the Future : Science, (Rev. Charles E. Raven), *review* by T. Raymont, 284
Renal Tubule : Apparent Reversal of Position of the Golgi Element in the (Major J. F. A. McManus), 417
Repeating Pattern : Binocular Focusing on a (Nellie Henderson), 726
Research in Aeronautics : Education and, 429
Research in Ulster : Archæological, 561
Research in the West Indies : Biological (Dr. V. J. Chapman), 47
Research : Cancer, 26
Research (*Cancer*) : Abstracts from, Vol. 1, 1941, 212
Research on Coal, 323
Research : Coke and Coal (Prof. H. L. Riley), 323 ; (Dr. R. A. Mott), 323
Research (Educational) : Foundation for, 717
Research (Engine) : The Chemical Background for (edited by R. E. Burk and Oliver Grummitt), *review* by Prof. D. M. Newitt, 675
Research in Australia : Fisheries, 110
Research (Fuel) : Collaboration in, 532
Research in the United States : Grassland (Prof. D. B. Johnstone-Wallace), 165
Research in Great Britain : Industrial, 16
Research on Early Man in Burma (M. C. Burkitt), 335
Research in South Africa : Marine Biological, 515
Research in War-Time : Medical (Sir Edward Mellanby), 500
Research in the Crown Colonies : Nutritional (D. Fitzgerald Moore), 418
Research at Oxford : Ophthalmological, 323
Research : The Role of Physical Optics in (Prof. J. K. Robertson), 362
Research in Free China : Parasitological (K. Chang), 699
Research on Metre Waves : Radio, 83
Research in the British Empire (Scientific) : Co-operation in, 29
Research in Great Britain : Scientific, 129
Research in Australia : Scientific and Industrial, 729
Research in India : Organization of Scientific and Industrial, 639
Research (Virus) : Recent Advances in, *review* by Prof. Wilson Smith, 584
Research (Vitamin) : Historical Development of Microbiological Methods in (Dr. Mary Sandford), 374
Research Activities in the United States : War and Post-War Integration of (Dr. R. H. Heindel), 212
Research and Education in Great Britain : Industry, 579
Research and Industry : X-Rays in (Dr. H. Hirst), *review* by Dr. W. A. Wood, 145
Research and Planning, 141 ; (Prof. M. Polanyi), 217
Research and Ships' Antifouling Paints (Dr. P. Ewart Bowles), 159 ; (Dr. G. D. Bengough), 159
Research and the Universities in Reconstruction, 641
Researches on Penicillin, 604
Resins and Allied Plastics : Synthetic (edited by Dr. R. S. Morrell), second edition, *review*, 398
Resources of the Sea, *review* by Sir D'Arcy W. Thompson, 647
Respiration (Normal) : Relation of Tea 'Fermentation' to (E. A. Houghton Roberts), 77 ; (H. B. Sreerangachar), 661
Responsibilities of Scientific Societies (Dr. Hubert Martin), 533
Retina : The Vertebrate, *review* by Dr. Katharine Tansley, 61
Reverberation in Small Glass Tubes (Shaun M. Cox), 357
Rh-Factor of Blood (P. Levine), 632
Rh-Factor in the Blood of a 48-mm. Embryo : Demonstration of the (F. Stratton), 449
Rh Genotypes in Man (Dr. R. R. Race, Dr. G. L. Taylor, Miss Kathleen E. Boorman and Miss Barbara E. Dodd), 563
Rh-Positive People : A Serum that Discloses the Genotype of some (Dr. R. R. Race and Dr. G. L. Taylor), 300
Rheology in the Textile, Leather, Shoe and Allied Trades (British Rheologist's Club discussion on), 272, 514
Rhesus Reaction : Mutation and the (Prof. Lancelot Hogben), 721
Riboflavin : Microbiological Assay of (Dr. Frank C. Happold), 414 ; (Dr. E. C. Barton-Wright and R. Gordon Booth), 414 ; (Prof. R. H. Hopkins), 724
Riboflavin and Vitamin B_1 in Nineteenth Century Buns and Ale (Dr. E. C. Barton-Wright, Dr. T. Moran and H. S. Sarson), 273
Riboflavin and Vitamin B_1 in War-Time Beers (Prof. R. H. Hopkins), 274
Ribonucleic Acids in Animal Tissues (Dr. J. N. Davidson and Miss C. Waymouth), 47
Rickettsial Agglutination : Specific Diagnosis of Typhus Fever by (Prof. I. J. Kligler and E. Olejnik), 627
Rinderpest in Africa : Barricade against Spread of, 296
River Boards (Third Report of the Central Advisory Water Committee), 576
River Control in Britain, 576
Robin : The Life of the (David Lack), *review* by Prof. Julian Huxley, 5
Rock Burst Experiments at Lake Shore Mines, Kirkland Lake (Dr. E. A. Hodgson), 362
Rocks (Eruptive), their Genesis, Composition, Classification and their relation to Ore-Deposits (Dr. S. James Shand), revised second edition, *review* by Dr. G. W. Tyrrell, 433
Roof Trusses made with Wooden Disk Dowel Joints (Timber) : Detailed Design of (V. D. Limaye), 242
Root Crops and Vegetables : The Production of Seed of (Imperial Agricultural Bureaux), 410
Roots of Crop Plants : Competition for Nitrogen between the Take-all Fungus and the (S. D. Garrett), 417
Roots of Mountains : Seismological Evidence for (Prof. Beno Gutenberg), 576
Roots (Excised Tomato) : Ten Years of Growing (Dr. Philip R. White), 125
Rose Hip Powder : Spray-Dried (Dr. V. L. S. Charley and A. Pollard), 354
Rotation and the Plough, *review* by Dr. Hugh Nicol, 118
Rothamsted Centenary (H. V. Garner), 128
Royal Institution (Thomas Martin), *review*, 491
Royal Medals of the Royal Society awarded to Sir Harold Spencer Jones and to Dr. E. B. Bailey, 559, 665
Royal Society and its Homes (Sir Henry Dale), 649
Rubber : New Synthetic, 297
Rubber in Europe : Production of, 747
Rubber-yielding Dandelions in Sweden, 131
Rubber Industry : A Pioneer of the, 130
Rubber Research Laboratory : Bell Laboratories (F. S. Malm), 157
Rugosity of Granular Solids (Robert H. S. Robertson and Barbara S. Emödi), 539
Rumex Acetosa : A Y-linked Inheritance of Asynapsis in (Dr. Askell Löve), 358
Rural Economy in Yunnan : Three Types of (Li-Yu-I, Hsiaotung Fei and Tse-yi-Chang), 195
Rusinga, Kenya : A Miocene Anthropoid Mandible from (Dr. L. S. B. Leakey), 319
Russia (Soviet) : Science in (J. G. Crowther), 138
  see also under U.S.S.R.
Russian Interest in Mathematical Statistics, 185
Russian Men of Science (British and) : Exchange of Greetings between, 70
Rye : Stripe Smut of (W. A. R. Dillon Weston and R. Eric Taylor), 160
Rye Grass Pasture (Perennial) : A New Water-Soluble Polysaccharide from (R. J. McIlroy), 724

S*ABELLA-PAVONINA* : Osmotic Regulation in (Dr. D. W. Ewer and R. F. Ewer), 598
Sabethine Mosquitoes of the Americas (Dr. John Smart), 279
Sal (*Shorea robusta*) : How to Distinguish between the Sapwood and Heartwood of (Dr. K. Ahmad Chowdhury), 193
Sal and Teak : Investigations into, 193
Saline (Hypotonic) : Fragility of Erythrocytes in (A. C. Roy), 599
Salmon : Obstructions to the Ascent of, 753
Salmon of the River Corrib, together with Notes on the Growth of the Brown Trout in the Corrib System (Arthur E. J. Went), 332
Salmon of the River Shannon (Arthur E. J. Went), 696
Salmon and Sea Trout of the Waterville (Currane) River (Arthur E. J. Went and T. Sankey Barker), 332
Salts and Sodium Hexametaphosphate (Long-Chain Cation-active) : Reaction between (Dr. J. Powney), 76
Saluting an Astronomer (Joseph R. Habes), 473
Samoa (south-west of) : Earthquake on March 15, 101
Samoan Islands (Phœnix and) : Fishes from the (Leonard P. Schultz), 511
San Francisco : Earthquake on October 26, 720
Sarcoma (Dibenzanthracene Mouse) : Long-term Cultivation *in vitro* of a (Dr. F. Jacoby), 299
Saskatchewan : Willows of (Prof. W. P. Fraser), 108
Saving and Spending : War-Time Pattern of (Charles Madge), *review* by Lieut. T. H. Hawkins, 257
Scenery : South African (Dr. L. C. King), *review* by Dr. P. E. Kent, 59
Schistosomes in Uncommon Sites (Male) : Identification of (Dr. F. Gordon Cawston), 477
Scholarships : Miners' Welfare National, 298, 596
Schoolboys : War-Time Growth of (E. M. Billington, Dr. R. A. McCance and E. M. Widdowson), 187
Schoolchildren (Canadian) : A Survey of (Dr. R. E. G. Armattoe), 391
School Children (Toronto Elementary) : A Height and Weight Survey of, 1939 (N. Keyfitz), 391
Science : The Autonomy of (Prof. M. Polanyi), 143
  Archæology as a (Prof. V. Gordon Childe), 22 ; (J. Reid Moir), 359
  Adult Education in (Dr. W. A. Waters), 359
  Education in World Ethics and (Sir Richard Gregory), *review* by T. Raymont, 284
  Forward with (Prof. Rogers D. Rusk), *review* by Prof. J. A. Crowther, 341
  The Freedoms of (Sir Robert Watson-Watt), 543
  The Rising Tide of, *review* by Prof. J. A. Crowther, 341
  Time Perspectives in (Prof. A. E. Heath), 434
  The Way and Spirit of (Generalissimo Chiang Kai-Shek), 180

'Scorched Earth' in the U.S.S.R. : Rehabilitation of the, 424
Scotland : Vital Statistics of, 243
Sculptures in the Madras Government Museum : Amaravati (C. Sivaramamurti), *review* by E. J. Thomas, 87
Sea : Resources of the, *review* by Sir D'Arcy W. Thompson, 647
Seaport : The Population of a (Exhibit by the National Museum of Wales), 656
Seaweeds : Nature and Uses of (Dr. E. Marion Delf), 149
Second Legion : Glevum and the, Part I (Charles Green), 219
Secretory Mechanism of the Digestive Glands (Prof. B. P. Babkin), 363
Sediments of the Dead Sea (Bottom) : Bacteria in the (Dr. B. Elazari-Volcani), 274
Seed of Root Crops and Vegetables : The Production of (Imperial Agricultural Bureaux), 410
Seed Crops : Spatial Isolation of (Gordon Haskell), 591
Seed Selection in Forestry (Prof. H. G. Champion), 354
Seed-borne Infection : A Case of Club-Root of Swedes due to a (Dr. L. G. G. Warne), 509
Seedless Fruits of Fertility and Conference Pears (M. B. Crane, A. G. Brown and D. Lewis), 24
Seeds : Appearance of Glutathione during the Early Stages of the Germination of (Sir Frederick Gowland Hopkins and Edward James Morgan), 288
Seismograph at the National Astrophysical Observatory at Tonanzintla, Mexico : Dedication of, 272
Seismological Evidence for Roots of Mountains (Prof. Beno Gutenberg), 576
Selby Lecture for 1943 (Sir Harold Spencer Jones), 408
Selenonium Salt : An Optically Active (Dr. F. G. Mann and F. G. Holliman), 749
Sensitivity of the Ear (W. A. Munson), 453
Serum Composition (Variation of) with the Age of Horses as shown by Electrophoresis (Dr. Alfred Polson), 413
Sewage Filters : Biological Control of the Fly Population in (T. G. Tomlinson), 52
Sewage Sludge : Vacuum Filtration of (J. M. Wishart, C. Jepson and L. Klein), 249 ; (J. H. Garner), 418
Sex Education and Guidance, 582
Sex Hormone Therapy : A Glossary of Terms used in (*Pharmaceutical Journal*), 534
Sex Ratio affected by Host Plant (E. McC. Callan), 162
Shannon (River) : Salmon of the (Arthur E. J. Went), 696
Sharp Eyespot of Wheat caused by *Corticium* (*Rhizoctonia*) *Solani* (Mary D. Glynne and Wendy M. Ritchie), 161
Shell Fish-hooks of the Californian Coast (Eugene Robinson), 419
Shipping Risks in Peace-time : Radiolocation and, 688
Ships' Antifouling Paints : Research and (Dr. P. Ewart Bowles), 159 ; (Dr. G. D. Bengough), 159
Ships' Names : Astronomy in, 18
Shoe and Allied Trades : Rheology in the Textile, Leather, (British Rheologists' Club discussion on), 272, 514
Shrew and the Field Mouse : Tularæmia in the (Glen M. Kohls and Edward A. Steinhau), 632
Siam (H. G. Diegnan), (Smithsonian Institution War Background Studies, No. 8), 72
Siderocytes in Mammalian Blood (Robert A. M. Case), 599
Sidey Summer-time Award (Royal Society of New Zealand), 352
Silicates of the Perovskite Type of Structure (H. J. Goldschmidt and J. R. Tait), 356
Silver Compounds as Fungicides (Lowell W. Nielsen), 511
Sinhala Weapons and Armour (P. E. P. Deraniyagala), 364
Siphonaptera : North American (H. E. Ewing and Irving Fox), 130
Siricidæ or Wood-wasps : Studies in (R. B. Benson), 24
Skeletal Remains from Cultural Associations from the Chicama, Moche and Virú Valleys, Peru (T. D. Stewart), 332
Skill (Manual) : Culture and (C. W. Hansel), 513
Sky (Night) : in August, 131 ; in September, 243 ; in October, 353 ; in November, 502 ; in December, 624
Sleepers : Treatment of Green Hollong (*Dipterocarpus macrocarpus*) (D. Narayanamurti), 242
Slip and Twinning in Single Crystals of Mercury (A. Fisher), 567 ; (Prof. E. N. da C. Andrade), 567
Smallpox : Rapid Disappearance of, 747
Smut (Stripe) of Rye (W. A. R. Dillon Weston and R. Eric Taylor), 160
Soap Solutions of Carcinogenic Hydrocarbons : Aqueous (Dr. Stephan Beck), 537
Social Biology : Some Aspects of (Sir Walter Langdon-Brown), 466
Social Development : Colonial Labour and (Prof. Daryll Forde), 203
Social Environment (Changing) : Science and its (Prof. P. W. Bridgman), 85
Social Influences upon Art : Impact of, *review* by F. Ian G. Rawlins, 31
Social Life in the Primates : Relation between Body-size, Waking Activity, Size of Eye-balls, and the Origin of (Prof. M. F. Ashley Montagu), 573
Social Order : Reconstruction of the, 351
Social Sciences : Studies of Twins in the (Joan C. Squires), 437
Social Sciences in Great Britain, 669
Social Studies and World Citizenship (L. J. F. Brimble and Frederick J. May), *review* by J. A. Lauwerys, 339
Society (Dynamic) : Leadership in a, 85
Society : Industry and, 1 : Relation to the Nation, 458 ; 2 : Relation Government, 486
Sociological Value of Family Meals (Prof. J. H. S. Bossard), 271
Sociologist : Obiter Dicta of a, *review* by Prof. George Catlin, 287
Sodium Hexametaphosphate : Reaction between Long-Chain Catio active Salts and (Dr. J. Powney), 76
Soft Bodies : A New Criterion for Expressing the 'Intensity of Firmness' (Dr. G. W. Scott Blair), 412
Soil (The Determination of the Electrical Properties of) at a Wavelengt of 5 Metres (Frequency 60 Mc./s.) (Dr. J. S. McPetrie and J. Saxton), 84
Soil Ciliate : Anabiosis in a (John M. Watson), 693
Soil Conditions in the Plant Pot (A. G. Pollard and C. W. R. Smith), 4
Soil Moisture (Value of the *p*F Scale of) for Expressing the Soil Moistu Relations of Wireworms (A. C. Evans), 21
Soil Moisture Relations of Wireworms : Value of the *p*F Scale of So Moisture for Expressing the (A. C. Evans), 21
Soil Moisture and Wilt Disease (Colin D. McKeen), 107
Soil Pests of the Potato (G. Fox Wilson), 633
Soil and Plant Analysis (Dr. C. S. Piper), *review*, 370
Soils (Certain British) : Sterol Contents of (G. E. Turfitt), 332
Soils (Tropical) : Conservation of Humus in (Dr. A. Sreenivasan), 572
Solar Corona and Geomagnetism (M. Waldmeier), 44
Solar Prominences and Sunspots in 1937 : Observations of (M. Marti Lorón, R. Carrasco and E. Gullón), 25
Solar Spectrum : Resolution of the Carbon Dioxide Bands at $2{\cdot}01\mu$ an $2{\cdot}05\mu$ in the (A. Adel), 361
Solar System : Non-Solar Planets and the Origin of the (Dr. H. Alfvén), 72
Solids (Granular) : Rugosity of (Robert H. S. Robertson and Barbara Emödi), 539
Solubility of Metals in Mercury (C. H. Prescott), 108
Sound : An Oscillographic Method for the Determination of the Velocit of (J. M. A. Lenihan), 661
South African Scenery (Dr. L. C. King), *review* by Dr. P. E. Kent, 59
South Georgia (east of) : Earthquake on March 9, 158
Soviet Russia : Science in (J. G. Crowther), 138
  see also under U.S.S.R.
Soviet War-Time Surgery (Dr. G. Lapage), 756
Soya Bean in Low Iron Concentrations : Growth of (M. S. Weiss), 361
Space-Heating Engineer : British Climate and the (R. Grierson), 213
Spain : Earthquakes registered during May and June, 382
Spanish : General Astronomy in, *review*, 89
Spanish Iron and Steel Industry, 755
Spanish Metallurgy since the National Movement (F. Mijlan), 755
Species : Area and Number of (Dr. C. B. Williams), 264
Species Hybrids in Drosophila : Transmission of Susceptibility to Carbo Dioxide to (Dr. H. Kalmus), 692
Spectra in Medicine : Absorption, *review* by Dr. R. A. Morton, 342
Spectra and their Applications : Molecular (Dr. Andrew McKellar), 362
Spectra of New Stars (Dean McLaughlin), 754
Spectra (Stellar) : An Atlas of (W. W. Morgan, Philip C. Keenan and Edit Kellman), *review*, 147
Spectra : Stellar Continuous (Barbier and Chalonge), 697 ; (J. L. Greenstein), 697
Spectrophotometry in Medicine (Dr. Ludwig Heilmeyer), translated b Dr. A. Jordan and T. L. Tippell, *review* by Dr. R. A. Morton, 342
Spectrum : The Coronal Line (P. Swings), 754 ; (Edlén, —.), 754
Spending (Saving and) : War-Time Pattern of (Charles Madge), *review* b Lieut. T. H. Hawkins, 257
Sperm reaches the Archegonium in *Pellia epiphylla* : How the (Prof. Joh Walton), 51
Spermatozoa *in vitro* (Rabbit) : X-Irradiation of (E. C. Amoroso and Dr A. S. Parkes), 244
Sperms in the Woodlouse *Armadillidium vulgare* Latr. : Length of Life o (H. W. Howard), 331
Spirit of Science : The Way and (Generalissimo Chiang Kai-Shek), 180
Spitsbergen : Geographical Distribution of *Arenaria humifusa* Wahlenb. New to the Flora of (Dr. Nicholas Polunin), 451
Sporangia of Cœlomomyces Keilin : Germination of the (Dr. Botha De Meillon and J. Muspratt), 507
Spore-forming Bacteria in Potatoes (Dr. W. J. Dowson), 331
Sprouting of Potato Tubers (Dr. Maurice Copisarow), 275
St. John's Wort in Australia (R. M. Moore and A. B. Cashmore), 746 ; (F. Wilson and T. G. Campbell), 746
Staff College for the Civil Service, 99
Stannous Sulphide : Semi-conducting Properties of (Merial C. Clark and J. S. Anderson), 75
Staphylinidæ of the West Indies (Richard E. Blackwelder), 219
Stars : Guide to the (Dr. Hector Macpherson), *review*, 63
  Photovisual Magnitudes of Double (A. W. J. Cousins), 512
  Spectra of New (Dean McLaughlin), 754
B8–B9 Stars : Photo-electric Colorimetry of (V. Nikonov and E. Brodskaja), 746
Stars in Daylight : Photography of (M. Waldmeier), 158
Statements make Predictions ? : Do all, 623
Statistical Methods in Engineering : Fluid Mechanics and (Hugh L. Dryden, Theodore von Kármán, Anton A. Kalinske, Thomas K. Sherwood, Samuel S. Wilks, Walter A. Shewhart, Leslie E. Simon and Roscoe Pound), *review*, 119
Statistical Tables for Biological, Agricultural and Medical Research (Prof Ronald A. Fisher and Dr. Frank Yates), second edition, *review* b Dr. J. Wishart, 491
Statistics : The Advanced Theory of (Maurice G. Kendall), Vol. I, *review* by Prof. R. A. Fisher, 431
  "Student" and the New Biological, *review* by Dr. K. Mather, 551
  Russian Interest in Mathematical, 185
  (Vital) of Canada, 186
  (Vital) of Scotland, 243
Statistics in the Field of Public Opinion Research : The Limitation of (J. G Ferraby), 44
Steel Industry (Iron and) : The Spanish, 755
Stellar Spectra : An Atlas of (W. W. Morgan, Philip C. Keenan and Edit Kellman), *review*, 147
Stellar Continuous Spectra (Barbier and Chalonge), 697 ; (J. L. Greenstein) 697
Stellar Spectrophotometry in the U.S.S.R. : 746

tereomorphism in Cryptic Coloration of Lepidoptera (Dr. B. N. Schwanwitsch), 508
teric Hindrance and Heats of Formation (Dr. A. G. Evans and Prof. M. Polanyi), 738
teroids : Acyl Migration in (V. A. Petrow, O. Rosenheim and W. W. Starling), 25
Sterol Contents of certain British Soils (G. E. Turfitt), 332
Sterols : Microbiological Degradation of, 332
Stilbamidine in Aqueous Solution : Instability of (Dr. A. J. Henry), 690
Stone Age Industries in Burma (Hallam L. Movius, Jun.), 335
Stones of Southern Africa : The Bored (A. J. H. Goodwin), Part 4, 658
Stonyhurst : Earthquakes registered during May, 45 ; during June, 353
Stored Food Products : Common Insect Pests of (Dr. H. E. Hinton and Dr. A. Steven Corbet), 272
Stored Products : Diurnal Activity of Three Insect Pests of (Dr. R. F. Ewer), 133
  Tyroglyphid Mites in (M. E. Solomon), 632
Strange New World, the Adventures of John Gilbert and Ludwig Leichhardt (Alec H. Chisholm), *review* by Prof. F. Wood Jones, 286
Strategy of Peace : Food and the, 1
Stripe Smut of Rye (W. A. R. Dillon Weston and R. Eric Taylor), 160
Structural Analysis and Design : Elementary (Dr. Linton E. Grinter), *review* by Prof. A. J. S. Pippard, 260
Structural Changes in Cold-worked Metals : New X-Ray Evidence of the Nature of the (Dr. H. Lipson and A. R. Stokes), 20
Structure of α-Keratin (Dr. Ian MacArthur), 38
"Student's" Collected Papers (edited by E. S. Pearson and John Wishart), *review* by Dr. K. Mather, 551
Sub-Atomic Physics (Prof. Herbert Dingle), *review* by Dr. L. F. Richardson, 7
Sub-Crustal Structure in the New Zealand Region from Seismic Data (R. C. Hayes), 512
Substitute Materials in War and Peace (Dr. C. H. Desch), 184
Substitutes and Synthetics : Encyclopedia of (edited by Morris D. Schoengold), *review*, 709
Succinic Acid : Synthesis of (M. S. Kharasch and M. T. Gladstone), 512
Sucrose : Mechanism of Polysaccharide Production from (Shlomo Hestrin and Mrs. S. Avineri-Shapiro), 49
Suffering : Medical Research in War-Time and the Relief of, 500
Sugars (Glycosides and) : Configuration of (E. M. Montgomery, N. K. Richtmyer and C. S. Hudson), 361
Sulphapyridine on Penicillin (Para-aminobenzoic Acid and) : Synergistic Effect of (Dr. J. Ungar), 245
Sulphide (Stannous) : Semi-conducting Properties of (Merial C. Clark and J. S. Anderson), 75
Sulphonamides : Medical Use of (Medical Research Council War Memorandum No. 10), 561
Sulphur Dioxide : Determination of Ascorbic Acid in the Presence of (Dr. L. F. Levy), 599
Sulphur Springs of Cyprus (Dr. M. Tamari), 277
Sulu Sea north-east of Borneo : Earthquake on June 9, 186
Sun : Eclipse on August 1, 131
  Eclipse of September 21, 1941, in the U.S.S.R., 658
Sun Chief, the Autobiography of a Hopi Indian (edited by Leo W. Simmons), *review* by Mrs. K. Rishbeth, 34
Sunspots in 1937 : Observations of Solar Prominences and (M. Martin Lorón, R. Carrasco and E. Gullón), 25
'Supernatural' : 'Natural' and (G. N. M. Tyrrell), 325
Surface 'Memory' in a Carboy (Herman A. Liebhafsky and Lester B. Bronk), 695
Surgery : Soviet War-time (Dr. G. Lapage), 756
Survey (Photographic) of Galactic Clusters (George Alter), 220
Sweden : Food Situation in, 213
  Rubber-yielding Dandelions in, 131
Sweden during 1942–43 : Rations and Food Consumption in (Carin Boalt and Yngve Zotterman), 635
Swedes (A Case of Club-Root of) due to a Seed-borne Infection (Dr. L. G. G. Warne), 509
Sweet Clover Hybrids (W. K. Smith), 696
Switchgear Testing : Design of Alternators for (V. Easton), 576
Sylvester Medal of the Royal Society awarded to Prof. J. E. Littlewood, 559, 667
Symbionts of Insects as a Source of Vitamins : Intracellular (Dr. G. Fraenkel and M. Blewett), 506
Symmetry of Basic Beryllium Acetate : Change of (Dr. C. A. Beevers), 447
Symons Gold Medal for 1944 of the Royal Meteorological Society awarded to Dr. C. W. B. Normand, 596
Synthesis of some α-Acyltetronic Acids (Wilson Baker, K. D. Grice and A. B. A. Jansen), 108
Synthesis of a 42-Chromosome Wheat, 575
Synthesis of New World Archæological Finds, 577
Synthesis of Succinic Acid (M. S. Kharasch and M. T. Gladstone), 512
Synthetics (Substitutes and) : Encyclopedia of (edited by Morris D. Schoengold), *review*, 709
Synergistic Effect of Para-aminobenzoic Acid and Sulphapyridine on Penicillin (Dr. J. Ungar), 245
Syphilis in the United States (Dr. W. G. Smillie), 243
Syrian Hamster : Vitamin C Requirements of the (Dr. Donald F. Clausen and Prof. William G. Clark), 300
Szechuan (Western) : Science in, 1 : Physico-Chemical Sciences and Technology (Dr. Joseph Needham), 343 ; 2 : Biological and Social Sciences (Dr. Joseph Needham), 372

TABLES (Statistical) for Biological, Agricultural and Medical Research (Prof. Ronald A. Fisher and Dr. Frank Yates), second edition, *review* by Dr. J. Wishart, 491
Tablet Absorption and Ghost Formation (Dr. S. J. Folley), 134
Tachycardia (Paroxysmal) : Etiology of (Dr. Richard F. Öhnell), 216
Tail in the Craniata : Conception of the (Beni Charan Mahendra), 163
Take-All Fungus and the Roots of Crop Plants : Competition for Nitrogen between the (S. D. Garrett), 417
Tameness of Varieties of the Norway Rat : Degree of (C. E. Keeler), 107
Tanganyika (Lake) : A Transverse Zoo-geographical Barrier on the East Side of (R. E. Moreau), 569
Tank-Breeding Mosquitoes in Portsmouth (John F. Marshall), 18
Tannin : Cacao (E. C. Humphries), 569
Tariffs : Foreign Trade and, *review* by Prof. J. G. Smith, 521
Taxonomy of the Moths Infesting Stored Food Products (Dr. A. Steven Corbet), 742
Tea 'Fermentation' to Normal Respiration : Relation of (E. A. Houghton Roberts), 77 ; (H. B. Sreerangachar), 661
Teak (Natural and Plantation) : Interim Report on the Relation between Rate of Growth and Strength of (V. D. Limaye), 193
Teak (Sal and) : Investigations into, 193
Technical Colleges : Future of (R. M. Barrer and J. P. Andrews), 80, 131, 387 (E. B. Moullin), 191 ; (Dr. H. Lowery), 218 ; (Dr. D. S. Anderson), 388 ; (Lawrence W. Kershaw and D. Humphrey), 388 ; (Dr. H. Schofield and H. Garratt), 450
  University of London External Examinations and the (Sir E. Graham-Little), 478
  Technical Colleges : Future of, 519
Technical Literature into Great Britain : Importation of (Dr. K. R. Webb, E. W. Balson, S. H. Harper and Dr. I. G. M. Campbell), 479
Technical Societies and Institutions of the United States and Canada (Scientific and) : Handbook of (U.S. National Research Council), fourth edition, 562
Technologist Looks at the Future (Dr. C. R. Burch), 523
Technology in English–French–German–Spanish (Science and) : Dictionary of (Dr. Maxim Newmark), *review*, 709
Telecommunication (Sir A. Stanley Angwin), 501
Telegraphy (Facsimile) : Train Orders by (J. H. Hackenberg), 719
Telescope, Microscope and Barometer as a Point of Departure for the Natural Sciences (Prof. Louis C. Karpinski), 719
Telluric Bands ω_1 and ω_2 : Resolution of the, 361
Temperature of Flame Gases (Prof. W. T. David), 278
Temperature Gradients in Gaseous Explosions (Dr. A. S. Leah), 303
Tennessee Valley Authority, an Achievement of Democratic Planning (Dr. Julian Huxley), 73
Terminology of Nucleic Acids (Dr. A. W. Pollister and Dr. A. E. Mirsky), 692
Termites of Australia (Dr. A. D. Imms), 27
Termites (Isoptera) from the Australian Region (Gerald F. Hill), 27
Tetraploidy in Cultivated European Potatoes : Nature of (C. H. Cadman), 103
Tetrapyrrolic Pigments (Biochemical Society discussion on), 534, 714
Textile Fibres under the X-Rays (Dr. W. T. Astbury), *review* by F. Ian G. Rawlins, 90
Textile, Leather, Shoe and Allied Trades : Rheology in the (British Rheologists' Club discussion on), 272, 514
Tharus and their Blood Groups (D. N. Majumdar), 332
Thebes : American Excavations at, *review* by R. O. Faulkner, 199
Thermal Scattering of X-Rays by Crystals (G. H. Begbie and Prof. Max Born), 19 ; (Dr. K. Lonsdale), 20
Thiourea on the Development of the Amphibian : Effect of (Dr. Albert S. Gordon, E. D. Goldsmith and Prof. Harry A. Charipper), 504
Thrips Resistance in Cacao (Dr. E. McC. Callan), 332
Thunderstorms and their Electrical Effects (Charles Chree Lecture of the Physical Society by Brigadier B. F. J. Schonland), 46
Thyroid-active Iodinated Proteins : Stimulation of the Milk Production of Dairy Cows by Feeding (K. L. Blaxter), 751
Timber : The Coming of Plywood, a Revolution in the Utilization of, 651
Timber Roof Trusses made with Wooden Disk Dowel Joints : Detailed Design of (V. D. Limaye), 242
Timber Seasoning Kilns suitable for Drying Indian Woods : Types of (M. A. Rehman), 242
Timbers : American, *review* by Alexander L. Howard, 259
  How to Identify, Part 3 (K. A. Chowdhury), 605
  Sources and Identification of, *review* by Alexander L. Howard, 144
Timbers for Aircraft and other Purposes : Recognition of Decay and Insect Damage in (Bulletin of the Department of Scientific and Industrial Research), 18
Timbers of the New World (Prof. Samuel J. Record and Robert W. Hess), *review* by Alexander L. Howard, 144 ; (Prof. Samuel J. Record), 602
Timbers of the United States : Commercial (Prof. H. P. Brown and Prof. A. J. Panshin), *review* by Alexander L. Howard, 259
Timbers (Indian) : Studies in Fire Resistance of some (D. Narayanamurti and R. Gopalachari), 605
Time Bases (Scanning Generators), their Design and Development (O. S. Puckle), *review* by L. Bainbridge-Bell, 116
Time Perspectives in Science (Prof. A. E. Heath), 434
Time (Our) : Diagnosis of (Karl Mannheim), *review* by Prof. George Catlin, 287
Time and Chance, the Story of Arthur Evans and his Forebears (Joan Evans), *review* by Sir Frederic Kenyon, 673
Timiriazev Centenary Celebrations, 138
Toledo : Earthquakes registered during August, 624
Tomato Growing : The Science of, 757
Tomato Roots (Excised) : Ten Years of Growing (Dr. Philip R. White), 125
Tool-tips : X-Rays in the Study of Sintered Carbides used for (L. D. Brownlee), 543
Toronto Elementary School Children, 1939 : A Height and Weight Survey of (N. Keyfitz), 391
Torricellian Experiment (Dr. J. Patterson), 719
Torulopsis utilis : Preparation of a Giant Strain of (Dr. A. C. Thaysen and Muriel Morris), 526
Tory Medal of the Royal Society of Canada awarded to Prof. John L. Synge, 362
Town Planning and Full Employment : Housing, (F. J. Osborn), 443
Tractellum (The Term) in Flagellate Organisms (A. G. Lowndes), 51
Trade Regulations and Commercial Policy of the United Kingdom (Research Staff of the National Institute of Economic and Social Research), *review* by Prof. J. G. Smith, 521
Trade (International) : New Plans for (Institute of Statistics, Oxford, Supplement to Bulletin No. 5, Vol. 5), 560
Train Orders by Facsimile Telegraphy (J. H. Hackenberg), 719
Training for Engineers : Education and (Institution of Electrical Engineers report), 137
Training for Mechanical Engineering : The White Paper on Educational Reconstruction and its Impact on (Institution of Mechanical Engineers), 609
Transformers : Instrument (A. Hobson), 696

Transparent Water-in-Oil Dispersions—the Oleopathic Hydro-Micelle (T. P. Hoar and Dr. J. H. Schulman), 102
Transport : Use and Misuse of (Political and Economic Planning Broadsheet No. 211), 745
Tree : The Elm (Alexander L. Howard), 636
    The Plane (Alexander L. Howard), 421
Trehalose : A New Source of (Dr. J. Leibowitz), 414
Trillium erectum : Interlocking of Bivalents in (S. G. Smith and E. R. Boothroyd), 219
Trimerous Perianth : Origin of the (Prof. A. C. Joshi), 695
Tropical Diseases : Modern Drugs and (Dr. F. Hawking), 204
Tropical Soils : Conservation of Humus in (Dr. A. Sreenivasan), 572
Truth : Science, Christianity and (Dr. Julian S. Huxley), 79 ; (Dr. Norman R. Campbell), 192 ; (C. D. Hardie), 192 ; (Dr. C. Berkeley), 479
Trypan Blue and Cell Migration in the Adrenal Cortex of Rats (Italo Calma and Charles L. Foster), 536
Tuberculin Proteins (F. B. Siebert and J. W. Nelson), 25
Tuberculosis in Buenos Aires (Dr. Alejandro A. Raimondi), 243
Tularæmia in the Shrew and the Field Mouse (Glen M. Kohls and Edward A. Steinhau), 632
Tunicates in the Plankton of Southeastern Australian Waters and their Place in Oceanographic Studies : Pelagic (Dr. Harold Thompson), 110
Turkey : Earthquake on June 20, 17, 382
    The Recent Earthquake in (Ernest Tillotson), 684
Twinning in Single Crystals of Mercury : Slip and (A. Fisher), 567 ; (Prof. E. N. da C. Andrade), 567
Twins in the Social Sciences : Studies of (Joan C. Squires), 437
Typhoid Fever : A Precipitin Test for (Lt.-Col. S. S. Bhatnagar), 448
Typhus : Distribution of, 382
Typhus in Palestine, 658
Typhus Fever by Rickettsial Agglutination : Specific Diagnosis of (Prof. I. J. Kligler and E. Olejnik), 627
Tyroglyphid Mites in Stored Products (M. E. Solomon), 632

ULSTER : Archæological Research in, 561
Ultra-High Electromagnetic Frequencies (Dr. G. C. Southworth), 54
Ultra-Short Wave Field-Strength Measuring Equipment : The Design of (F. M. Colebrook and A. C. Gordon-Smith), 83
Ultra-Violet Light and Apparent Vitamin C (Dr. Frank Wokes), 328
Ultra-Violet Irradiated Yeast Cells : Relation of Nucleotides and Nucleosides to Proliferation-Promoting Factors produced by (Prof. Elton S. Cook, Sr. Ann Gertrude Cronin, Cornelius W. Kreke and Sr. Thomas Mary Walsh), 474
Ultra-Violet Rays : Colour Microscopy in (E. M. Brumberg), 357
Ultra-Violet and Daylight Rays : Variations of (Dr. J. R. Ashworth), 330
Uniocular Threshold of Vision : Binocular and (Dr. Maurice Henri Pirenne), 698
Unit of Energy : James Prescott Joule and the (Prof. H. S. Allen), 354 ; (A. W. V. Mace), 418 ; (Graham Renshaw), 418 ; (J. H. Awbery), 479 ; (W. and R. Chambers, Ltd.), 479 ; (Prof. J. B. S. Haldane), 479 ; (Dr. K. R. Webb), 602 ; (Prof. C. H. Lees), 602 ; (Prof. W. Peddie), 602
United Kingdom : Trade Regulations and Commercial Policy of the (Research Staff of the National Institute of Economic and Social Research), *review* by Prof. J. G. Smith, 521
United Nations : Education and the (Report of a Joint Commission of the London International Assembly and Council for Education in World Citizenship), 169
United Nations Conference on Food and Agriculture, 67
United States : Agricultural Crops of the, *review*, 522
    Agricultural Education in the (Prof. R. Rae), 166
    Sudden Rise in Birth-Rate in the, 158
    Grassland Research in the (Prof. D. B. Johnstone-Wallace), 165
    Penicillin in the, 605
    Poliomyelitis in the, 688
    War and Post-War Integration of Research Activities in the (Dr. R. H. Heindel), 212
    Early Science in the, 657
    Syphilis in the (Dr. W. G. Smillie), 243
    Commercial Timbers of the (Prof. H. P. Brown and Prof. A. J. Panshin), *review* by Alexander L. Howard, 259
United States Department of Agriculture : Organization of Scientific Research in the, 380
United States Army Medical Corps : Ornithologists of the (Colonel Edgar Erskine Hume), *review*, 61
United States and Canada : Handbook of Scientific and Technical Societies and Institutions of the (U.S. National Research Council), fourth edition, 562
Universities in Great Britain : Post-War Needs of, 595
Universities in Reconstruction : Research and the, 641
University : Redbrick (Bruce Truscot), 549
University in Modern Life, 548
University of London External Examinations and the Technical Colleges (Sir E. Graham-Little), 478
University Physics (Dr. F. C. Champion), Part 5 : Electricity and Magnetism, *review* by Dr. L. F. Richardson, 7
Urease by Penicillin : Inhibition of (Lt.-Col. Joseph C. Turner, Capt. Frederick K. Heath and Boris Magasanik), 326
Urease Activity and Ascorbic Acid (Dr. J. H. Quastel), 215
Urease Activity by Ascorbic Acid : Inhibition of (L. A. Elson), 49

FOOD AND THE STRATEGY OF PEACE

THE United Nations Conference on Food and Agriculture which has just ended at Hot Springs, Virginia, brought together representatives of forty-four nations to consider the world problem of food distribution after the War. It has been described, not inaccurately, by the editors of *Fortune* as the first of the peace conferences to end the War, and for the first time in history we are witnessing the planning of the strategy of peace while the objectives of war are still far from their fulfilment. The Conference has yet to be followed by action, it is true, but on its face value its declarations and decisions give reasonable ground for the belief that an important blow has been struck for sanity in world economics.

The recommendations show that most of the time and expert knowledge of the delegates to the Conference were devoted to the problem of providing more and better food for 2,000 million people to eat. Almost all their proposals for the expansion of production, the improvement of nutrition and the increase of consumption are specifically directed to this end. The prior charge on each country will be to provide the foods of high nutritional value such as milk, other dairy produce, vegetables and fruit, which are mostly perishable and best produced as near as possible to the centres of production. The want and need of these protective foods is almost unlimited. Beyond this basic domestic priority, consumption needs must be met from the most efficient sources of production wherever they may be found, with specific safeguards for the conservation of soil and its fertility.

Essentially this programme is a manifesto for freer trade and the international division of labour. Equally it is a programme of full employment—the development of industries and of purchasing power in backward areas as well as the maximum output of the right foodstuffs in the right places. It is not a policy of *laisser-faire* or of cut-throat competition, and although guarantees of stable prices to efficient producers to prevent the collapses which have been a bane in the past are essential to success, the protection of producers and restriction of supply by high tariffs or quantitative restrictions on imports must be firmly excluded. The protection of consumers and the maintenance of demand by social security measures or subsidies to special classes must be the weapons of policy.

The principal decision of the Conference is the creation of a permanent international organization, on the lines of the International Labour Organisation, to secure collaboration on measures to increase production, distribution and consumption of food. Until the permanent organization can be established, an interim commission is to function in Washington, meeting not later than July 15. This Commission will be responsible for the promotion and co-ordination of research, and for the collection and dissemination of information. It will submit to the individual Governments recommendations for action along the lines agreed by the Conference, and will examine such questions as the development of agricultural resources, commodity arrangements, consumer co-operatives, land tenure and other subjects considered at the Conference.

Besides this section concerned with the permanent machinery to implement its recommendations, the Conference was organized in three other sections, each divided into a number of committees, responsible for examining particular aspects of the general problem.

The report of the first section, on consumption levels and requirements, stresses the relation between malnutrition and poverty and gives a picture of "world-wide under-consumption, malnutrition and its attendant evils". Three-quarters of the 1,150 million inhabitants of Asia are living below decent health standards; malnutrition exists among the lower income groups of the United States and Europe; there are widespread deficiencies in tropical Africa, the West Indies and other colonial territories, and the War has aggravated a situation already serious. Without formulating a uniform set of dietary standards for general application, certain broad principles are laid down, and such standards as those evolved by the League of Nations Technical Commission on Nutrition are universally applicable. Advances in nutritional science permit the establishment of minimum dietary requirements in terms of calorie, protein, mineral and vitamin content. Government promotion of systematic education in food values, special provision for pregnant women, nursing mothers, infants and adolescents and the development of community services, school meals and factory canteens are recommended.

The second section, which examined the expansion of production and adaptation to consumption needs, distinguishes between the short-term and the long-term objectives. First, it recommends an immediate increase wherever possible in the acreage of crops for direct human consumption, even at the expense of postponing the replenishment of livestock herds. While the shortages continue, the governments, individually and collectively, should endeavour to co-ordinate national production policies and the means of transport and distribution, and should take measures to prevent speculation and price fluctuations. Countries which, owing to their freedom from the impact of war, have been producing more than their normal output should maintain or expand their production and develop the manufacture of farm machinery and fertilizers.

The period of transition will involve considerable adjustments in policies. The long-term policy of each nation should be to increase the efficiency of production through better farming methods, measures for soil conservation, the encouragement of research, and the exploitation of undeveloped areas through land clearance, drainage and irrigation projects; and to introduce changes designed to foster the production at home of protective and relatively perishable foodstuffs. Nations should not attempt artificially to produce nutritionally desirable foods which can easily be obtained elsewhere. Besides measures designed to improve agricultural efficiency and promote research, this section of the Conference recommends that, to facilitate occupational adjustments, countries with large populations in relation to their agriculture should develop suitable industries for processing and preserving their own produce, and should be assisted to export processed articles rather than raw materials, and to import machinery and tools.

The recommendations of the third section, on the facilitation and improvement of distribution, are less definite, depending as they do on international agreement in the wider field of reconstruction. The Conference recognizes that the key to the long-term problem lies in full employment, with generally increased purchasing power and improved standards of living. The need for maintaining a balance between agriculture and industry is recognized, and international trade barriers and restrictions are denounced. In the immediate post-war period it will be necessary to ensure the most economic distribution of available supplies and to avoid price fluctuations and unrestrained competition. Under-nutrition will necessitate international action on a large scale, and international commodity arrangements will be necessary: these should allow effective representation of consumers, the maintenance of adequate reserves and the orderly disposal of surpluses. Other recommendations are international standardization in methods of processing, preserving, storing, packing and transport; measures for protecting the consumer from unfair trade practices; and full use of such war-time developments as dehydration.

So much for the general programme, the technical soundness of which can scarcely be questioned. The translation of recommendations into action, however, involves the overcoming of long-standing political obstacles, national and sectional. While, for example, the maintenance of health in Britain during the War shows what can be achieved through a scientific nutrition policy and the planned distribution of basic foodstuffs, in Britain no less than elsewhere agriculture is unbalanced and distorted, and with vested interests created in uneconomic farming. The farming forced on nations by war-time scarcities and the severance of communications is poles apart from the programme of abundance that co-operation and common sense could devise in a peaceful world, and is dangerously close to the narrow nationalistic aspirations of politicians and producers.

That is the first issue upon which the Governments of the world must fasten. To translate into specific terms this vision of an efficient and fruitful world agriculture, based on the expansion of world production according to a functional division of tasks, will demand not only all the help that the proposed permanent international organization can give it, but also the understanding support of public opinion everywhere. That the public interest must overlay discussion is a principle that must be firmly applied. Fortunately there are already welcome signs that education in this matter is proceeding apace. The recent *Fortune* report on "Relations with Europe" is an American example. Recognition of the importance of widening the areas of free trade and, when the

Anglo-American and the European free-trade areas are well established, linking them and making them one, together with the recognition that reparations should be limited to payments in kind—the only reparations that make economic sense—are far in front of the outlook of 1919. On European economic and agricultural development the proposals of this *Fortune* report are strikingly in line with the broad trend of the Conference recommendations, and it is to be hoped that progressive opinion in Great Britain will not only welcome these proposals and recommendations but also lose no time in formulating a post-war agricultural policy in harmony with them.

The second point which requires emphasis is that the Conference reconnoitred only one sector of a large front. Originally it was intended that the Conference should confine its attention to post-war problems, but while in response to many appeals it considered also problems close at hand, it was not directly concerned with the relief measures that will be needed as new areas are liberated from the Axis. It could not ignore the problems of production which must be solved if food supplies on the scale needed to relieve hunger are to be forthcoming, but the Conference can only rightly be regarded as the forerunner of other conferences of the United Nations, the work of which will be complementary to its own in laying down the strategy of the peace.

Food strategy is only a part, though an essential part, of that wide strategy, and the new world organization to be set up will provide the indispensable general staff for research, discussion of policy and advice to Governments. It will provide the centre for the collection of statistics and information and the co-ordination of policies. Such an organization is the more essential in view of the third point that stands out from the briefest review of the work of the Conference, namely, the intimate relation of this food strategy to the strategy of the attack on the problems of unemployment, disease and other evils which stand in the way of the realization of freedom from fear and from want. So far as Great Britain is concerned, this involves the special issues put forward in the Scott Report and ultimately in the Beveridge Report. Raising the standard of living and nutrition among all the nations must have profound effects on the domestic policy of every country in agriculture. Indeed the Conference enables us to glimpse something of the framework for a policy of general advance—for the establishment of full employment and social security.

We are brought, therefore, once more to realize that, complex as are the many problems involved in the establishment of a world order of full employment, social security and freedom from want, none of the interlocked problems can be considered in isolation. We must always have regard to the wider background, national and international, into which our decisions and policies have to fit. Moreover, as the work of the Conference clearly shows, it is that wider view that really gives us hope of a solution. Seen against the background of the Hot Springs Conference, assumption *C* of the Beveridge Report has a reasonable prospect of fulfilment, and we may well hope that in further discussions on the Barlow Report, the Scott Report and the Beveridge Report, and in the overdue decisions as to the policy to be pursued, this larger background will not be forgotten but will assist in the formulation of bold policies and sound but courageous strategy.

There is evidence that this wider view is gaining acceptance. It is well put by Oswald Stein, chief of the Social Insurance Section, International Labour Office, in an article, "Building Society Security", which has recently been reprinted from the *International Labour Review*. Viewing the place of social security services in post-war reconstruction, he points out that such services should be conceived as an interdependent whole, intended to take care of, preserve and develop labour forces by ensuring their maximum productivity, and also their fair share in material progress even when their period of active participation in production has passed. Moreover, social security is limited to the aims of preventing and controlling the common risks of life, and meeting those needs which are not only vital for the individual but at the same time essential for the moral and economic welfare of society as a whole. Such limitations exclude any collective guarantee tending to diminish the vital assets of individual effort and initiative.

Into this same framework fit the cardinal objectives outlined in the *Fortune* report: peace through a common military security; freedom through a common bill of rights; prosperity through a common economic life, while here, as in the draft agreement for establishing the United Nations Relief and Rehabilitation Administration, is also the recognition that relief and rehabilitation will give the United Nations their first chance to transform their military alliance into a peaceful alliance with humanitarian and constructive aims. The relief scheme is the essential preliminary to the long-term programme of the Hot Springs Food Conference for realizing a world free from want, and it is at least a hopeful portent that the suggestions should come from an American periodical that the pooling of transport and communication facilities involved in relief and rehabilitation should be a step to the permanent unification of transport, and that the reappearance of autarchic tariffs, which clearly will not be allowed to interfere with the import of military and relief goods, should be postponed for ever.

Further evidence of the trend of American opinion can be found in the declaration adopted by the delegates of twenty-one countries at the Inter-American Conference on Social Security at Santiago de Chile in September last, which related social security to the full achievements of the four freedoms and set forth a continental programme as well as visualizing a contribution to world solidarity and the attainment and maintenance of peace. In Great Britain a recent Planning broadsheet, "Employment for All", which cannot be analysed here, makes an important contribution to the discussion first of the guiding principles of a policy for full employment and second of the operation of those principles in the setting of the immediate post-war years. Even more important is the draft agreement for the creation of a United Nations Relief and Rehabilitation Administration which the United States Government, after consultation with the British, the Soviet and the Chinese Governments, has recently put before the United Nations.

This comprehensive plan for administering relief in the wake of the armies of liberation is of importance in relation to food strategy, for several reasons. It is the first step towards a balanced economy in which a high level of consumption will prevent the piling up of great stocks of surplus goods in all the primary producing countries. Relief and rehabilitation is the opening phase of the post-war era, and the recent address of Herbert Lehman, at present director of the Foreign Relief and Rehabilitation Operations of the United States, who is expected to be the first director-general of the new organization, shows how American opinion is facing the situation.

Secondly, the proposals, like those of the Food Conference, indicate a clearer understanding of the continuity of war and peace. All such schemes imply the retention for some time after the War of controls over food, raw materials and transport, as well as some of the national rationing schemes. The organization of common action for peace as for war must be based on the pooling of available resources and a common policy, and a common control to govern their distribution. It should be the business of every citizen of goodwill to promote that understanding, and the Food Conference and the relief agreement supply abundant material for that work—a task which admittedly the British and American Governments should themselves undertake with more vigour and less diffidence than they have hitherto shown.

A third encouraging sign is not merely the shift in emphasis from the political and constitutional to the social and economic factors in post-war reconstruction, but also the attempt to work out the implications of this shift in emphasis on an international scale. These attempts to provide for the immediate needs of food, medical supplies and clothing, and then for the reconstitution of the economic life of Europe in a way offering means of livelihood to its peoples for the future, are far more urgent and far more hopeful than the fixing of frontiers, establishment or re-establishment of constitution and conclusion of international pacts which preoccupied the peace-makers at Versailles. The functional and strictly practical character of the organizations now being set up by the United Nations as the framework of their continued co-operation after the War encourages the hope that the lessons of the past are being learned. If further, profiting again by the failure in 1918 to use such tried machinery as the Allied Transport Council and Food Council, we turn to our post-war purposes such organizations as the various Combined Boards for Food, Shipping, Production and Raw Materials, and the regional organizations such as the Middle East Supply Centre, there should be every reason for confidence that, with the help of all this experience and this established machinery for advice and execution, it should be possible to gain time for the creation and growth of new loyalties and combinations of interest, in addition to national ties. Such an outlook will be of immense importance when the time comes for the establishment of new internationa organizations endowed with full authority to dea with problems of health, food and agriculture, which can only be effectively handled over areas transcending national frontiers. Large as may be the responsibilities of the world's Governments, there still lies on each citizen the responsibility of endeavouring to understand the implications of the situation and of assisting his fellows to grasp it. By these means full support may be obtained for necessary action, even if it may appear to threaten sectional or even narrowly national interests. This is not to suggest that love of one's country is a thing of the past. There is still room for patriotism, but there must in addition be love of humanity; one can surely be built up on the well-tried foundations of the other, to provide an edifice in which there is safe lodging for world understanding and peace.

EDUCATION: FOR WHOM AND FOR WHAT?

SOME time ago a document which, rather inaccurately, became known as the Board of Education's "Green Book", was issued in order that ideas on the future shape of Great Britain's educational system might be discussed and clarified. Copies were not, for what seem to have been quite sound reasons, to be obtained by any save selected bodies. Almost inevitably, however, it appears to have become the most widely known 'secret' document of modern times. The result, nevertheless, has justified its preparation and circulation: for, ever since its issue, all kinds of bodies have embodied their own suggestions in pamphlets of varying hues. The National Union of Teachers was one of those bodies, and, more than a year ago, published its own "Green Book" under the title of "Educational Reconstruction".

The difficulty with all these documents, however, is that they are couched in the language—or is it the jargon?—which the expert tends to use when talking to other experts. Dipping at random among the pages we may find a sentence like this: "In the interim we recommend that the principles of the present Grant Formula, which is a combination of a per capita and percentage grant, be continued". That is, doubtless, an excellent recommendation, and its effect, if it be accepted, may profoundly influence the education and prospects of thousands of students. But it is very doubtful whether it will stimulate any great interest or excitement in the breasts of the majority of parents who want improvements in the educational opportunities of their children but know little or nothing of the intricacies of the system which should produce those opportunities.

Clearly, if educational reconstruction is to be successful, parents must know what it is all about and be anxious to see it put into operation. They cannot do that unless the matter be explained to them in simpler and less technical terms than are normally used by teachers and administrators.

For that reason we believe a new pamphlet issued by the National Union of Teachers meets a very definite need. Its main title is "A Plan for Education"; but it also has a sub-title which gets right to the heart of the matter: "The National Union of Teachers discusses with parents the Kind of Education they want for their children and how to get it".

The pamphlet explains that, since we are fighting for the democratic way of life, it is imperative that, in the very midst of the battle, we should plan such post-war conditions as will enable us to reap the fruits of victory. There are numerous aspects of the general plan now being prepared, but its base must be the provision of a good education.

What, however, is this 'good education' which all parents would like their children to have? The pamphlet answers the question not in a learned discourse but in simple sentences which he who runs may read. "There are few of us," concludes one paragraph, "who do not constantly feel a sense of our own limitation in the enjoyment of life and in the power to seize interesting opportunities when they come our way. We feel we are only half-educated." That is the kind of approach which ought to be successful because it says plainly what so many thousands of inarticulate people feel vaguely but never attempt to express.

In the same simple language this notion of a good education is amplified. The importance of physical as well as mental growth is brought out. "If you are not a hundred per cent fit and healthy, you can't enjoy life to the full." From that point of view the importance of nursery education, school buildings, the school medical and the welfare services are fitted to the picture.

Mental growth is obviously more difficult to assess, but the pamphlet goes on to explain why it is so often retarded. To that end causes in the present educational system which result in failures who ought never to be failures are indicated. Finally, the part played by inequality of opportunity is vigorously discussed. "Some children are taught in splendid buildings, others in disgraceful buildings; some in large classes, others in small; some stay at school until 18, others must leave at 14; some have the chance . . . of going to the university or technical college, others must work at uninteresting jobs . . . and feel defrauded all the rest of their lives."

But the matter is not allowed to rest there. The parents to whom the pamphlet is addressed are told that it is no use always blaming someone else for these shortcomings. If they want this "good education" for their children they must try intelligently to secure it. The job, they are told, comes back to them. "Not 'theirs', 'ours', is the task of seeing that the boys and girls of this generation have an education worthy of the democratic ideal for which their fathers are fighting."

If after so plain a statement, ordinary men and women who read the pamphlet still fail to turn their opportunities to account, the fault at any rate will not rest with those responsible for this pamphlet.

A STUDY OF THE ROBIN

The Life of the Robin

By David Lack. (Bird-Lovers' Manuals.) Pp. 200+6 plates. (London: H. F. and G. Witherby, Ltd., 1943.) 7*s*. 6*d*. net.

ORNITHOLOGY has made notable contributions to general biology during the present century. The student of species-formation, of adaptation, of animal population, of ecology, of behaviour, or of courtship and sexual selection cannot neglect the ornithological literature, for it is there that he is likely to find many of his clearest and best worked out examples. Field-work has been as important as museum or laboratory study, and the contributions of British field-workers have been among the most important.

Lack's book on the robin is in the best traditions of modern British ornithology. It is the result of intensive field observation, backed by scientific method and combined with experiment, and once again demonstrates how much of value there is to learn about our most familiar wild species.

He definitely explodes the myth that the parent robin fights with its young, and finally demonstrates that the elaborate posturing, so often described as courtship display, is found in both sexes, and is entirely concerned with aggressive threat towards intruders. He makes the interesting suggestion that the recrudescence of full song found in the robin and many other species, just after the young have left the nest but are still under parental care, is an adaptation to teach the young birds the proper song of the species. This suggestion could be checked by discovering whether this recrudescence of song is absent in species where the song does not have to be learnt in whole or in part, but is wholly innate.

His study of courtship in the robin has led him to an interesting extension of the idea first thrown out by the present reviewer thirty years ago, that the main biological function of certain types of courtship (for example, mutual display in grebes) lies in their providing an emotional bond between the pair. Lack is now inclined to think that courtship feeding, wherever it occurs, has a bond-forming function, as opposed to the stimulative function of display and certain symbolic actions. One is tempted to generalize this still further and to suggest that bond-forming courtship is likely to occur, in addition to stimulative courtship, in all or most bird species in which the co-operation of the pair is needed to rear the brood.

Lack's ringing methods have established that the British robin is partly migratory, and he suggests that it is in process of transition from a migratory to a non-migratory status. Extending the work of American ornithologists with stuffed mounts, he has shown that, although a robin is capable of extraordinary visual discrimination, such as the recognition of its mate at a considerable distance, yet its aggressive behaviour, normally directed against intruders on its territory, is elicited by the crude "signal" constituted by the red breast. While a stuffed adult whose red breast had been painted a dull brown failed to elicit attack, an isolated red breast, "sans head, sans wings, sans tail, sans everything", was attacked in fifty per cent of the trials. Like other intensive field-studies, but perhaps with special force, Lack's has demonstrated the extent of variability in temperament and behaviour: this constitutes an important section of the reservoir of evolutionary plasticity which is required if a species is to be able to meet changes in environmental conditions.

Some of Lack's difficulties over the theoretical interpretation of bird behaviour are perhaps exaggerated. The reviewer, for example, fails to see why repeated and intensified display should not be expected to act as a more efficient stimulus to an unresponsive mate (p. 72); or why a "drive" should not be as readily produced by natural selection as any other adaptation of functional organization (p. 171). But these are trivial points. Lack's book can be warmly commended not only to the general biologist but also to the layman interested either in birds or in biology. It is well illustrated, fully documented, interspersed with delightful titbits of historical information, and discusses many of the particular problems raised by the robin's behaviour in the light of a wide knowledge of the ornithological literature. It is eminently scientific, and also very readable. JULIAN HUXLEY.

GEM TESTING

Gem Testing for Jewellers

By B. W. Anderson. Pp. 220. (London: Heywood and Co., Ltd., 1942.) 7*s*. 6*d*. net.

As its author remarks in the preface, this book "has been written mainly with the ordinary jeweller and dealer in view". It is, indeed, a praiseworthy attempt to give the otherwise unaided layman a working knowledge of the physical methods and instruments commonly employed in gem testing and also to provide him with the necessary data on which to base his identifications. Mr. Anderson brings to the task a wide experience in gem testing, gemmological teaching and research, and jewellers are indebted to him for making available to them so much of his knowledge of precious stones in a readily assimilable form. There is much useful information for anyone interested in gem-stones, and the book is deserving of a wider public than its title suggests.

The twenty-three short chapters fall into two sections. In the first of these the necessary instruments and methods are described in simple but clear language and with sufficient detail to enable the novice to master them without other assistance. Refractometers, dichroscopes and colour filters, specific gravity methods, microscopes and spectroscopes are discussed, and advice is given on the purchase of suitable equipment. A chapter on the detection of synthetic stones is included in this section.

The remaining chapters deal with the identification of gem-stones and other gem materials. In each case the specific characteristics of the material under consideration are discussed, then the methods for their determination, those involving the minimum of apparatus being given first. Finally, possible imitations and other gems with which that under discussion may be confused are examined. At the end of each chapter is a useful table listing the properties of the group just considered. That his method of treatment amounts to a classification based on colour is recognized by the author, who discusses its defects in some detail. While some will certainly dissent, the reviewer is inclined to agree with the author in thinking that the end justifies the means. Those who disagree will appreciate an alphabetical summary of gem species provided in the appendix, which also contains a glossary, notes on the crystal systems, a list of useful books with brief reviews and specific gravity and refractive index tables.

Of the forty-three illustrations, about half are photomicrographs of inclusions and other internal and surface features of natural and synthetic stones. These give a very clear idea of the phenomena and form a valuable adjunct to the text.

A very full index (about 700 items) adds considerably to the usefulness of the book, which is in bold, clear type on good-quality paper and, with the exception of the 23-page advertisement supplement, is a pleasing production.

THE FIRST STAGE FROM BARBARISM

The Making of Modern New Guinea

With Special Reference to Culture Contact in the Mandated Territory. By Stephen Winsor Reed. (Memoirs of the American Philosophical Society, Vol. 18.) (Issued in co-operation with the International Secretariat, Institute of Pacific Relations.) Pp. xix+326. (Philadelphia: American Philosophical Society, 1943.)

PUBLICATION of this report has been delayed through the outbreak of war with Japan. The research was carried out in 1936 on behalf of the Institute of Pacific Relations, the object being to discover the effects of contact with Europeans upon native cultures in the Mandated Territory of New Guinea. A previous report in 1928 dealt with proposed methods of carrying out the administrative policy towards the primitive Papuan tribes; the present inquiry is on the actual changes attributable to the influence of Europeans.

Beginning with the landing of early explorers, foreign influences are carefully traced to the present day by references to the abundant literature on New Guinea. More than half the volume consists of this interesting and valuable material from records of pioneers, travellers, traders, miners, squatters, missionaries, government officials, etc., both before and after the Germans assumed rights over the Territory, and finally under the administration of the Australian Commonwealth.

In order to gain first-hand experience of native cultures, the author accompanied an American anthropologist, Dr. J. W. M. Whiting, to the Upper Sepik and studied a mountain tribe, the Kwona, for six months. Later, three months were spent in observing the lives of natives who were in direct contact with white men.

Chapter 7 concerns the very difficult and controversial questions of the reaction of the Papuan to white man's culture.

The author has not made it sufficiently clear at the outset whether he considers the ultimate aim of the Commonwealth should be the welding of Papuans and Europeans into a corporate community, or the administration of a plural society without any social unit interfering unduly with another. It depends upon which view is taken as to how far the Australian Government is supposed to have fallen short of its ideal.

As a paternal Government putting the rights of the Papuans before all else, the author admits that the Government has undoubtedly made great efforts in the face of many difficulties, but he is of the opinion that the form of education given to the natives is not calculated to prepare them for independence or self-government, which should be the aim of all democratic governments. He considers also that the superiority of Europeans ought not to be so strongly emphasized as in the relative positions of master and subordinate, and he does not agree with the Australian insistence upon a colour-bar.

This personal attitude is observable in the author's approach to problems in the latter part of the report, where he describes the sophisticated native and his adaptation to new conditions in a general survey of the semi-civilized population of employees, dependent upon many introduced commodities and living in close contact with Europeans.

The volume is valuable as a contribution of material from all sources to form a basis for the inquiry, but it is uncertain that the inquiry has actually been answered. For where such delicate problems as changes in innate cultural beliefs are in question a far more critical investigation of factors seems to be necessary, as well as an anthropological approach to these subjects. Further, information obtained through the clumsy linguistic medium of pidgin-English needs to be very carefully checked on any occasion, but particularly in matters which the Papuan has difficulty in expressing even in his native tongue.

There are slight errors. On p. 82 it is stated that British annexation of the South-East Territory followed the German, but actually the reverse is the case. On p. 260 a paper relating to castes is quoted, but this was written upon the natives of the Solomon Islands and not those of New Guinea, among which those castes do not exist.

P. 29, "fermented drinks are completely absent in New Guinea" ; also in the footnote—the only mention of kava is from the Admiralty Group. Wollaston recorded that the fermented sap of the sugar palm (*Arenga saccharifera*) was being drunk by natives in the South Division, Netherlands New Guinea ("Pygmies and Papuans", 1912, chapter 8). Kava is made in the Western Division, Papua ("Handbook of the Pacific Islands", 1921).

L. EVELYN CHEESMAN.

SHORTENED PHYSICS

(1) Mechanical Physics

By Prof. Herbert Dingle. (Nelson's Aeroscience Manuals.) Pp. 248. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1942.) 5*s*. net.

(2) Sub-Atomic Physics

By Prof. Herbert Dingle. (Nelson's Aeroscience Manuals.) Pp. 272. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1942.) 5*s*. net.

(3) University Physics

By Dr. F. C. Champion. Part 5: Electricity and Magnetism. Pp. vii+246. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1942.) 7*s*. 6*d*. net.

PROF. DINGLE'S two small books form a balanced course of physics, not including mechanics. They begin at the post-matriculation stage, assuming a slight knowledge of mechanics and of the calculus, and they attain a level, on the standard of the University of London, somewhere between the physics of Intermediate Science and that of the General B.Sc. They treat ordinary academic physics and are not specially "aero". The explanations are easily read and almost all very clear, the diagrams abundant and satisfactory, the paper good, the print excellent, and the price low. There are indexes and exercises. A welcome addition to the usual course of physics is a chapter on sidereal and solar time, with diagrams of the celestial sphere. An original feature is the broad grouping of the subject-matter into "mechanical" and "sub-atomic" books; the former including gravitation, elasticity, surface tension, viscosity, heat and sound; whereas the "sub-atomic" book includes optics, electricity and magnetism. In explanation of this arrangement the second book has a chapter on the structure of the atom. But it is placed at the beginning, at a stage where the student cannot yet understand the experimental evidence. This dogmatic chapter may whet the appetite of some students, but discourage others.

In the optical section the focal-length of a converging lens is taken to be negative, contrary to the convention recommended in 1934 by a committee of the Physical Society.

There are a few mistakes which should be rectified before students believe them: It is fused silica, not quartz as stated on **1**, 109, which has a much smaller coefficient of expansion than glass. It is contrary to chemical usage to state, as on **2**, 17, that "the halogens (fluorine, chlorine, etc.) . . . are strong bases". Inside a permanent magnet there is reason to believe that the vector which flows continuously, without reversal at each pole, is the induction, and not, as stated on **2**, 184, the magnetic force. The unit of magnetic intensity is dynes per unit pole, and not simply dynes as stated on **2**, 209.

Dr. Champion's book covers the syllabus in electricity and magnetism of the London General B.Sc. It begins at the amber-and-lodestone level and proceeds rapidly, by using the calculus and by extending from easily understood examples to bold generalizations. The electron is introduced at an early stage as a tentative hypothesis. There are plenty of diagrams, most of them quite simple and clear. But where clarity can only be attained by perspective, or other graphic elaboration, the diagrams are of various quality, and a few are unsatisfactory, namely those of the post-office box, of the attracted disk electrometer and of the cathode ray oscillograph. Engineers as a class set a good example to physicists in the art of drawing apparatus.

The print is good, the paper fair; there is an index; there are exercises at the end of each chapter, and a hundred quantitative problems, followed by hints and answers, towards the end of the book.

Beginners are apt to be bothered by the standard argument about the mechanical force on a charged conductor. Dr. Champion does it with apparent ease (p. 23) by putting a unit charge in a small hole in the conductor. But is this novel argument valid without much fuller analysis? Surely the field inside the hole is far from uniform.

This book will get the student through his examination. But we are often told that one of the chief advantages to be gained from a scientific education is the insight into scientific method, and a critical habit of judging evidence. Books of the present compressed type, such as (1), (2) and especially (3), that have been printed during the paper-shortage for the use of students attending shortened courses, are more likely to form the habit of jumping to conclusions in obedience to some phrase of authority, such as: "Now clearly . . ." Various matters on which the physicists of former generations had serious doubts, which they settled by prolonged experimentation and argument, tend to be presented to the war-time student as if they were intuitively obvious. Of course, the transition from original notebook, through research pamphlet, to text-book must always involve an enormous rejection and much compression. But let us hope that, when conditions are favourable, there may be a return to the style in which more of the romance and discipline of past researches and controversies is retained.

The dogmatism of Dr. Champion's otherwise clear and readable text will be remedied, so far as the mathematical aspect of the subject is concerned, if the student will work through the hundred examples at the end of the book. As for the habit of judging experimental evidence, it is well that the universities insist on laboratory work. L. F. RICHARDSON.

PAPER MILL LABORATORY TECHNIQUE

A Laboratory Handbook of Pulp and Paper Manufacture

Incorporating the fourth edition of Stevens's "Paper Mill Chemist". By Dr. Julius Grant. Pp. viii+320+8 plates. (London: Edward Arnold and Co., 1942.) 28*s*. net.

MUCH of the technique of the paper mill laboratory is specialized and described only in papers distributed throughout an extensive literature: it is therefore useful to have in this single volume short descriptions of the most reliable methods of procedure, and references for those who wish to study any particular subject in detail. Probably because of an attempt to keep down the bulk of the volume, many of these descriptions are unfortunately rather sketchy and it is doubtful whether the mill chemist, approaching a given determination for the first time, could in all cases complete it successfully from the brief instructions given. For the same reason, the text is not very critical, nor does it discuss fully the difficulties which one is apt to encounter in practice; so that in general it conveys the impression that the determinations are easier to carry out than they really are. This book, then, should be regarded not as a substitute for a library, nor as a collection of instructions to be followed blindly on all occasions, but rather as a guide to methods and a pointer to sources of information.

In the first chapter, Dr. Julius Grant describes how the scientific worker in a paper mill has to have a good working knowledge of general chemistry, physics and chemical engineering, combined with a personality capable of winning and retaining the respect and confidence of the mill operatives. He has three main tasks. First, he has to examine thoroughly all new raw materials, and check deliveries from usual sources; unsatisfactory batches must not be allowed to reach the mill, and he will be expected to advise on the best way of utilizing materials which, though not up to standard, are nevertheless still usable. Secondly, he has to check the various stages of manufacture in order to guide the operatives in their work and ascertain whether the processes have been carried out efficiently. The third part of his duties is to examine customers complaints; and, where time and resources permit to conduct original research on paper problems Certainly a wide field.

The second chapter deals with the processes of isolating reasonably pure cellulose fibres from the raw materials, with sections on 'cooking', bleaching and the evaluation of cellulose, lignin, etc. Non-fibrous raw materials, such as lime and caustic soda, and the recovery of spent liquors, are discussed in the next chapter. Chapter 4 deals with the preparation and examination of standard test sheets made from the 'half-stuff' and the determination of its 'freeness', moisture content, etc. In Chapter 5, the various operations which take place in the beater house are considered, with special reference to the effect of beating, loading, sizing and colouring on the properties of the resulting paper. The final stages in the conversion to paper are described in Chapter 6. Here are sections on the care of the machine wire, drying cylinders and felts, and the examination of 'backwater'. The 'after-processes' considered include calendering, tub sizing, 'conditioning', coating, waxing and gumming. Paper testing by physical methods is described in Chapter 7. The importance of proper sampling and testing at a definite relative humidity and temperature is stressed, and most of the current tests for thickness, strength, colour, gloss, etc., are outlined. Testing by chemical and microscopical means is dealt with in the next chapter, which includes sections on loading and pigments, ash, acidity and *p*H, metals and acid radicals, cellulose and mechanical wood content, resins, and starch. The main microscopical tests are for fibre identification and furnish, and the determination and identification of dirt particles. The last chapter deals with tests for papers for special purposes, and contains short sections on statistical analysis of data and testing of water and fuel. A number of useful tables are contained in an appendix.

The text is clearly written apart from a few loosely constructed sentences, and there are a few grammatical errors: for example, "to 50 ml. of this *are* added sufficient ammonia" (p. 45); "papers which must *lay* flat" (p. 164). How far the use of numerals in text matter is permissible is always difficult to decide, but contractions like "between 2 rolls", "into 3 main categories" (p. 174) are surely unnecessary and ugly, except in abstracts. What few misprints there are seem to occur mainly among the numerals. The mean wave-length of white light is not 0·05 μ (p. 117); for a "narrow spectral range" 10 A., and not 1000 A., is intended (p. 204); and the "160 mm. objective" on p. 246 should read "16 mm. objective". It is unnecessary to give the viscosity of glycerol as 871.700 centipoises (p. 84) when it is to be used for calibrating a simple flow viscometer; three significant figures would have been ample.

The make-up of the volume is good, except in a few places. For example, Fig. 22, referred to on p. 194, is not inserted until facing p. 258, and the reader is given no indication where it may be found. With the general reservation that the book tends to suffer from over-condensation, it can be recommended. One hopes that the day is not far distant when it will again be possible to test butchers' wrapping paper (p. 272) with "slices of beef liver (2×4×0·5 in.)"! V. G. W. HARRISON.

SCIENCE IN SOUTH-WEST CHINA

I. THE PHYSICO-CHEMICAL SCIENCES

By DR. JOSEPH NEEDHAM, F.R.S.

British Council Cultural Scientific Mission in China

OWING to the course of the War and world conditions, Free China has now been isolated from the rest of the world for such a long time that an account of what our Chinese scientific colleagues have been doing will surely be of interest to readers of NATURE both in Britain and the United States. During the past few weeks, since my arrival, I have had excellent opportunities of seeing the work of Chinese men of science in all branches of their work, and the present opportunity of presenting a short account of it to the scientific workers of the other United Nations is an important one.

Kunming, the capital of Yunnan province, is an ancient Chinese city lying at the northern end of an extensive lake, in a large plain surrounded by mountains. The whole region, with its equable and sunny climate, both winter and summer, must be one of the most beautiful in the world, since the plain is not so large that the mountains are ever out of sight. An intensive agriculture is carried on, aided by an elaborate system of dykes and canals, their banks often raised high above the surrounding fields, and planted with pine-trees, conveying water from the mountain-sides, and dating from the Yuen Dynasty (about A.D. 1200). The scientific institutions are well scattered at different distances from the city, and transport is by horse-cart, charcoal-burning bus, 'jeep', lorry or car.

The National Associated South-Western University

The National Associated South-Western University (Hsi-nan Lien-ho Ta-Shioh), formed by a coalescence of Peiping, Chinghua and Nankai Universities, and perhaps the greatest teaching centre in Free China, has a campus not far from the city. President Mei Yi-Chi (the physicist) attends to internal and local affairs and President Chiang Mon-Lin (educationist) attends to outside affairs. Both are outstanding personalities, embodying the ideal of the Chinese scholar. All the departments are housed in 'hutments' built of mud brick, and roofed very simply with tiles or tin sheets, though some have curving roofs in the great tradition of Chinese architecture. Inside, the floors are beaten earth, with a little cement, and extreme ingenuity has been used in fitting up laboratories for research and teaching under these conditions. For example, since no gas is available, all the heating has to be done with electricity, and hence when the supply of element wire for heaters (home-made out of clay) ran out some time ago, work was at a standstill until it was found that gun lathe shavings from one of the Yunnan arsenals would do very well. When hæmatoxylin became unobtainable, it was found that a dye something very like it could be obtained from an orange-coloured wood native to Yunnan, *Cæsalpinia sappan*. When microscope slides could not be had, window-panes broken by air raids were cut up, and the unobtainable cover-slips were replaced by local mica. For glass-blowing, the blowpipes are fed with the vapour of power alcohol (derived from molasses) passed through electric furnaces. Instances could be multiplied at length.

The campus of the University lies in scenery somewhat resembling Upper Deeside, with its pine-trees and hills in the distance. There are no air-raid shelters, and the population scatters to the hills if a raid looks like being serious. Built into the floors of each mud-brick building are large petrol drums, and all the most valuable apparatus is lowered into these when the siren goes, in order to preserve it against anything but a direct hit. Even in its humble buildings, the Associated University has been bombed several times and many of the rows of huts destroyed.

In the Physics Department of the University (visited with Dr. Wu Yo-Hsün, dean of the Faculty of Science) the main research going on is on the distribution and other properties of cosmic rays, by Drs. Chao Chung-Yao and Ch'ang Wên-Yü (both from the Cavendish Laboratory, Cambridge). But as might be expected under present difficult conditions, more theoretical work is proceeding, and Dr. Wu Ta-Yo recently published an important book on the vibrational spectra of molecules, which was printed just before the fall of Shanghai, and a copy of which has been sent to the Cavendish Laboratory. Radio physics problems are being studied by Ma Se-Chun and Ma Ta-Yo, and mathematical physics, thermodynamics, etc., by Wang Ch'u-Hsi (a pupil of Sir Ralph Fowler) and Huang Tzu-Ching. Prof. Yao Yu-Tai (dean of the Faculty of Science at Peiping University) and Prof. Hsiung Ching-Lai had as their pupil the eminent young mathematician, Hua Lo-Kung, a collaborator of Prof. G. H. Hardy.

The chemical side is mainly directed by Profs. Yang Shih-Hsien and Tsêng Chao-Lun, both organic chemists. One of the principal problems is the investigation of the alkaloids and glucosides in the anti-malarial drugs of the classical Chinese pharmacopœia; this is of much importance in relation to the existing world quinine shortage. There is also a group working with Dr. Ch'u Rju-Hua at the Peiping Institute; her interest lies in the migration aptitude of groups in phenanthrene pinacol compounds, and in the possible relation of vitamin K to the sulphanilamide drugs. Prof. Tsêng and his collaborators are working on glycol lubricants. Unfortunately, as in all the other chemical laboratories I have seen here, the work is seriously hampered by lack of chemical reagents, and the supply of these seems almost more immediately necessary than the supply of books and periodicals. Chemical engineering is taught by Dr. Hsieh Ming-Shan (a pupil of Sir Alfred Egerton), and among the physical chemists is Chien Jen-Yuen (a pupil of Prof. C. N. Hinshelwood). It was a pleasure to see on the shelves of the working library a complete set of the *Journal of the Chemical Society* and other journals, presented by the University of Oxford.

Not all the research institutes of Peiping, Chinghua and Nankai Universities were absorbed into the United University. Out at Dragon King Pool, about two hours distant from the city, are some of the Chinghua Institutes, notably that of mineralogy and metallurgy (Dr. Wang Tsun-Ming), that of radio physics (Dr. Rjên Chih-Kung), and that of crystal physics (Dr. Yu Shui-Huang, a former collaborator of the Braggs). The first of these co-operates with the Yunnan Geological Survey in assaying the numerous interesting and rich ores newly discovered in the province, and has found new alloys with important thermo-electric properties. The second is occupied with telecommunications, and has complete apparatus for making experimental valves in these rustic surroundings. The third possesses good equipment, all made in Yunnan, such as a Debye-Scherrer powder crystal camera, Laue oscillating camera, etc. The altitude of Kunming (some 6,000 ft. above sea-level) is so high that the spark-gap setting is affected. These institutes have good workshops, but they would have very much better ones if financial support were available to set up and run some of the machines which were saved from the east or smuggled through the Japanese lines after the fall of Peiping and Hankow. There is also a great difficulty for all scientific institutions here, namely, that the university or Government wage for technical assistants is much smaller than what they can earn by going into business in a time of rise in prices which may truly be called gigantic. I shall have more to say on this subject in the following article.

National Academies

Besides the universities in China there are also two national academies: the Chinese National Academy (Chung Yang Yen Chiu Yuan) and the Peiping Academy (Peiping Yen Chiu Yuan). Of the ten research institutes of the former, three are located in the neighbourhood of Kunming, those of astronomy, chemistry and engineering. The astronomical observatory, exiled, alas, from its beautiful buildings on the Purple Mountain near Nanking, is situated a long way out in another direction from Kunming, at Big Tree Village. One of the members of the staff there is Dr. Tai Wên-Sai of Cambridge, formerly a collaborator of Prof. F. J. M. Stratton. The chemical institute is nearer town, and work is going on there on ultra-violet spectral analysis of organic and inorganic compounds, as well as on the active principles of local drugs, under the direction of Dr. Wu Shioh-Chou. The engineering institute is largely occupied with glass technology and metallurgical problems. Its workshop constructs all kinds of apparatus, such as kymographs and respirometers, for other scientific institutions.

The physics and chemistry sections of the Peiping Academy are located some three hours out, again in another direction, at a beautiful spot in the foothills near White Jade Hill. Here the physics section, under the direction of Dr. Ni Chi-Sse and Dr. Tsien Ling-Chao, has turned over almost wholly to war production, and a most remarkable plant for grinding lenses for microscopes, telescopes, etc., has been set up. The Academy is actually producing microscopes for teaching and research, having worked out all its own necessary apparatus, such as spherometers, etc. It is dependent on optical glass from England, however. Besides this, entirely new methods have been developed for making quartz piezo-electric crystals for frequency stabilization in radio work, and these are being produced in regular quantity, so that a supply may be available for the other United Nations. A point of interest here is that Dr. Tsien Ling-Chao has worked on the history of science in China, and has studied the optical chapters in the works of the classical Chinese philosopher, Mo-Tze (c. 400 B.C.). The Peiping Academy has also a section of chemistry, presided over by Dr. Liu Wei-Tao. Here also work is proceeding on the indigenous anti-malarial drugs by Dr. Wang Hsiu, an Austrian-trained organic chemist, and on the anthraquinone compounds of the rhubarb family.

Central Machine Works

Together with some of the members of the Peiping Academy, I paid a visit to one of the largest engineering works in China, the (State) Central Machine Works, which is established in a mountain valley in Yunnan, and employs thousands of workers. Here it was a remarkable sight to see the elaborate apparatus for making fine tools, gear wheels, and other engineering parts requiring high accuracy, hidden away from the risk of air bombing in tunnels and artificial caves in the hillside. In the depth of the mountain one could see a Chinese skilled worker checking the accuracy of the machining on a Zeiss universal measuring machine in a constant-temperature room. Or one could view a scene resembling the cavern of Hephæstus, except that the ovens were of the most modern gas-filled kind used for tempering machined steel parts. Elsewhere are a vast foundry and assembling shops. There is an impressive system of apprenticeship, with special shops for training the young fitters and machinists. The main output of the factory is primary machinery such as drilling, planing, milling, boring and rolling machines, which are supplied to arsenals and other works, and the finished products, standing in their rows, were very impressive. These works really deserve an article to themselves. The whole is under the direction of an engineer (a former physicist), Dr. Wang Shou-Chin. Dr. Wang's father, Dr. Wang Chi-Tong, now a venerable figure of seventy, is also interesting. Himself the son of a Hanlin scholar, he was one of China's first modern engineers, and is now in his retirement devoting himself to the study of Buddhism in relation to modern thought.

Description of the Central Machine Works affords an opportunity for mentioning one very hopeful sign observable there, namely, the effort on the part of the Chinese to get away from the bad side of their old traditions of scholarly aloofness from manual labour, and the old system of excessive politeness. In these works, fully trained university graduates in engineering are working side by side with the ordinary workers, taking active day-to-day charge of each special process and controlling every stage. This is really a change from the old graduate's attitude to practical work. The same improvement may be seen in the atmosphere at the National Vaccine Production Institute (the National Epidemics Prevention Bureau), directed by Dr. T'ang Fei-Fên. Here once a week, as a kind of communal exercise, all the workers of the Institute, including the medical men, bacteriologists, etc., as well as the glass-makers, the routine fillers and samplers, the stables staff, etc., join together in levelling and improving the site so as to convert it into a healthy garden.

Geology

It only remains to describe a little of the work of the geologists. The geologists of the Associated University (led by Profs. Sun Yuing-Ch'u, a former collaborator of Prof. J. E. Marr at Cambridge, and Yuan Fu-Li) work in close association with the Yunnan Geological and Mineralogical Survey, and together they have investigated large parts of the province. A picturesque old house in the country has been appropriated to the purposes of a museum, and there a very fine collection has been assembled, with separate sections for stratigraphy, ores, palæontology, etc. Yunnan is an area extremely rich in mineral resources, having admirable ores of antimony, arsenic, zinc, copper, iron, cobalt, tungsten and tin, as well as coal, lignite, rocksalt, asbestos and mica. Phosphate deposits are widespread, with phosphorus content as high as 38 per cent.

THE LISTER INSTITUTE OF PREVENTIVE MEDICINE

FIFTY YEARS RESEARCH ACTIVITY

By SIR JOHN LEDINGHAM, C.M.G., F.R.S.

THOUGH the British Institute of Preventive Medicine had received its certificate of incorporation under the Companies' Acts in 1891, it was not until two years later that its amalgamation with the College of State Medicine, with its rooms at 101 Great Russell Street, London, made possible its embarking on the scientific activities it was founded to promote. It is fitting, therefore, that short of celebrating in some more overt fashion, had times been normal, the jubilee of an institution which has well and worthily performed the charge committed to it by its founders, we should at least take the opportunity of recalling its genesis and of reviewing in briefest compass the services it has rendered to preventive medicine throughout a period which has witnessed that branch of science so bountifully enriched by the cultivation of all those basic studies that minister to its advancement.

The genesis of the British Institute of Preventive Medicine is soon told. A Mansion House meeting took place on July 1, 1889, to discuss the urgent problem of hydrophobia in Great Britain in the light of Pasteur's experimental work, and his elaboration of what had been almost universally hailed as a successful method of treating the victims of rabid dogs by immunizing them with his attenuated virus. At this meeting a resolution moved by Victor Horsley that the Government should be invited to introduce a Bill for the simultaneous muzzling of all dogs throughout the British Isles and for enforcing quarantine of imported animals was carried, and a son of Pasteur who attended the meeting was asked to convey to his father the thanks of the meeting for his services to British victims sent to Paris to undergo the new treatment. A committee was appointed to consider the most appropriate manner of discharging their debt to Pasteur and his staff for treating gratuitously "over 200 of our fellowcountrymen". Towards this object an appeal for funds was made, and the result was a gift of some two thousand pounds which was forwarded to Pasteur as a contribution to the Institute which bore his name and which had been formally opened only nine months previously (November 18, 1888). Funds were also raised towards the reimbursement to needy patients of their travel costs to Paris.

This was not all, however. The Committee enlarged its numbers and proceeded to consider how the lack of an institute in Great Britain with similar objectives to those of the Pasteur could be made good; and the final outcome of their deliberations, details of which cannot be given here, was the founding of the British Institute of Preventive Medicine, which received its charter on July 25, 1891. Long before this date, however, steps had been taken to secure sufficient funds to enable a commencement, even in a small way, of the Institute's programme of work. Financial support was solicited from private individuals and City of London companies, but progress was slow and indeed gave the promoters much concern, for provision had to be made not only for a scientific staff but also for the erection of a building worthy of the purpose it was destined to subserve.

Very substantial help came from the Berridge Trust and the Grocers' Company and this, together with private donations and the liquid assets of the College of State Medicine, with which amalgamation was effected in 1893, placed the British Institute of Preventive Medicine in command of invested funds of the order of £60,000, at least half of which was earmarked for building purposes. Temporary accommodation for staff and students was found in rooms at 101 Great Russell Street, the lease of which was taken over from the College of State Medicine, and here the work of the Institute was carried on under very restricted conditions until the move could be made in 1898 to the new building in Chelsea Gardens. On December 6 of that year the British Institute became the Jenner Institute, in fulfilment of a promise by the Council to the Jenner Memorial Committee, which had collected funds to commemorate in some fitting way the centenary of Jenner's great discovery, that such change would be made should the funds collected be placed at the disposal of the Institute. The sum handed over by the Committee amounted to £5,768 and, ever since, the revenue from its investment has been disbursed on behalf of a Jenner Memorial Studentship tenable at the Institute. Five years later, in 1903, constantly recurring difficulties arising from a prior claim to Jenner's name by a body trading as the Jenner Institute of Calf Lymph, necessitated a further change of name and it was decided, with Lister's consent, that the Institute should bear his name.

Since the Mansion House meeting, Lister had taken a leading part with Sir Henry Roscoe in all the difficult and tedious negotiations with Government departments leading to the incorporation of the Institute as an association limited by guarantee but permitted to omit the word "Limited" from its designation. He had publicly upheld the importance of animal experiment in opposition to the noisy objections of the anti-vivisectionists, and he had been president of the Council of the British Institute until that body ceased to exercise executive functions on its replacement by a governing body of seven members under the terms of the munificent gift (1899) of £250,000 to the Institute by Lord Iveagh, whose interest Lister had been largely instrumental in securing. This gift gave an immediate assured income of some £8,000 a year and made possible progress in many directions.

So far I have referred only to the main research building in Chelsea Gardens, but one of the earliest ventures was the organization by the Council of the British Institute of an experimental farm for serum production, particularly diphtheria antitoxin. Dr. M. Armand Ruffer, who was appointed interim director in 1894 after the amalgamation with the College of State Medicine, was able to report to his Council that in August of that year he had immunized one or two horses against diphtheria toxin. These first horses to be immunized in Great Britain were stabled at the Brown Institution, and valuable help with the technical arrangements was given on the spot by Horsley and Sherrington. Later in the year, the work was removed to Sudbury, and finally in 1902 transferred to Elstree, where the Serum Department of the Institute has since been located. This department has not only been of enormous value to the Institute in providing an additional source of income from the sale of biological products, particularly therapeutic sera, but has also proved an unequalled training ground for young members of staff and voluntary workers, native and foreign, eager to acquire a practical knowledge of immunological principles with the added advantage of working with large animals.

Further Developments

Developments of the Lister Institute since its inception have been concerned almost solely with the growth of departments, and the institution of new departments rendered desirable less by reason of completeness or mere yielding to custom, than by the availability of outstanding exponents to run them. Some departments have had short lives, while others, such as those of nutrition and biophysics, the latter a quite recent innovation, have obviously come to stay in view of their weighty contributions to preventive medicine in the widest sense. It may be of interest to note that in 1919 the Governing Body, then becoming anxious about the future financial state of the Institute in view of increased costs of research and a probable falling-off in trading profits, proposed to the members that the name of the Institute as shown in the articles of association be changed to the "Lister Institute of Medical Research", on the ground that the change would convey to all persons more clearly the nature of the work carried on in the Institute than the words "Preventive Medicine", and that consequently more public support in the form of additions to its permanent revenue might ensue. The motion, however, was lost at an extraordinary general meeting of the members held on June 11, 1919.

The proposal in 1914, by a majority of the Governing Body, to hand over the Institute to the Government, under certain conditions, as a nucleus of the research organization contemplated by the National Health Insurance Act of 1911, created wide interest both internal and external. At a specially called meeting on November 18, 1914, of members of the Institute, Sir Henry Roscoe in the chair, the proposal was keenly debated, the merits and demerits of State control being the main theme expounded by a succession of distinguished speakers. The motion to amalgamate was, however, lost by a narrow margin of votes.

The idea of having a research hospital attached to the Institute, of similar character to those at the Pasteur and Rockefeller Institutes, was *inter alia* considered by a Reconstruction Sub-committee of the Governing Body in 1919, and it was agreed to be a sound one. Steps were accordingly taken with the approval of members at specially called meetings to have the relevant item on treatment in the original memorandum of association altered by the Court to permit the building of an in-patients hospital for which ground adjacent to the Institute was available, provided that, for the establishment and maintenance of such hospital, only funds "as shall be specifically subscribed for that purpose" be employed. So far, the necessary funds for that purpose—and they would require to be very large funds—have not been forthcoming.

The Institute as a Scientific Centre

It is not for me, at least here and now, to traverse, much less to assay, the published work of half a century in a variety of fields. This must await a fuller history. Apart from the two specially printed volumes of dates 1897 and 1899 (London: Macmillan and Co.) containing papers published before the Institute adopted the name of Lister, there have appeared some forty volumes of "Collected Reprints", copies of which have been sent to selected individuals and scientific libraries in Great Britain and abroad. The very titles of the papers in these volumes will, as the years pass, be found to reflect very accurately the kind of problems that have exercised the minds of investigators at different periods, from the earliest activities of bacteriology, chemistry and immunology as the chief handmaidens of preventive medicine, to the advent of other disciplines such as biochemistry and biophysics which have come to the help of, and indeed would sometimes seem to dominate, current advance in fields which hitherto have been cultivated mainly on biological lines. I may mention, for example, bacteriology, immunology, nutritional science, endocrinology and virus structure. It is already clear that future workers in the field of preventive medicine, whatever form their particular biological training may take, will be well advised to add to their armamentarium a good deal more than a mere capacity to appreciate the help that chemistry and biochemistry can give to their problems; *mutatis mutandis*, I may add, for the trained chemist embarking on a biological problem.

Fortunately, in an institute containing experts in various disciplines, the difficulty of ensuring that the fullest light is thrown on a problem is considerably lessened. In the forty-two volumes to which I have alluded appear not only the fruits of inquiries planned within the Institute's walls but also scientific contributions and reports on a great variety of problems in the solution of which Institute workers have from time to time been invited to participate by various Government, public and scientific bodies. I may refer, for example, to such matters as the experimental demonstration of the rat flea as the vector of plague, the new knowledge of caisson disease and cognate issues made possible by the large pressure chamber, the gift of Dr. Ludwig Mond, the work on vitamins and deficiency diseases originally commenced in the middle of the War of 1914–18 to satisfy a crying need for special knowledge to meet an urgent war problem, and now with greatly expanded knowledge serving the present war effort at home and abroad, the investigation of the insect vector question in trypanosomiasis, yellow fever, typhus and trench fevers and many others.

Aside from its research activities, or perhaps because of them, the Institute has from its inception performed a most valuable function in providing research facilities for young workers from Great Britain and other countries desiring to acquire a working knowledge of technical methods, or to undertake under supervision some particular piece of work, holders of Beit and other fellowships, including those attached to the Institute, together with approved young graduates preparing for the higher research degrees of the University of London, with which the Institute has long been affiliated as a research school with its professors, readers and recognized teachers. Many of these former students and many former members of the Institute's staff have afterwards had distinguished scientific careers in academic or other spheres in various parts of the world. Having but recently retired from a lengthy term of service on the Institute's staff, I would wish to send here a friendly greeting to all former Listerians on this important occasion; and to offer, on behalf of NATURE, its congratulations to the Institute's Governing Body and staff, and its best wishes for the future work and welfare of the Institute in a post-war world.

ASCORBIC ACID IN DEHYDRATED FOODS

By DR. L. W. MAPSON

Dunn Nutritional Laboratory, University of Cambridge, and Medical Research Council

THERE is much evidence that titration against 2,6-dichlorophenolindophenol, provided it is done rapidly and in acid solution[1], gives results accurately agreeing with the biological estimate of ascorbic acid in common foodstuffs, including fruits and vegetables (both raw and as generally cooked), and in various animal tissues[2]. Even for most manufactured articles, such as jams, tinned fruits and various other processed foods, the chemical test has been shown to be generally applicable[2]. In a few exceptional instances, however, interferences from non-specific reductants may have to be allowed for. Such substances occur in caramelized and fermented products (for example, in malt extracts, or the products obtained by alkaline-heat treatment of sugars, in materials such as oats or pea mush after heat treatment, and in yeast and fermented juices)[3]. The substances known to interfere include stannous and ferrous salts, as well as sulphites, sulphides and thiosulphates, among inorganic substances, and reductones and reductic acid among organic compounds. Substances of the former class, however, are not normally present in foodstuffs, and moreover they can be fairly easily differentiated if desired. Thus, thiosulphate and sulphydryl compounds may be removed by precipitation with mercuric acetate[4], sulphite by treatment with acetone[5], or sulphides by conversion to hydrogen sulphide and removal *in vacuo*. Lugg[6] has recently recommended the use of formaldehyde to differentiate ascorbic acid from sulphides, sulphites, thiosulphates, quinones, sulphydryl compounds and reductones. It will be recalled that glutathione does not interfere under the conditions of the test[7], and that free cysteine is not normally a constituent of foodstuffs and in any event reacts so much more slowly that its presence would not be a source of serious error.

We became interested in the differentiation of ascorbic acid from reductones and allied compounds when evidence was found of their presence in certain dehydrated foods which had been subjected to heat treatment. These reductones, as would be expected from their chemical structure, resemble ascorbic acid in many ways ; they are more stable in acid and less stable in alkaline solution ; their oxidation is catalysed by copper and enzymes such as ascorbic acid oxidase ; and they give a current-voltage curve on the polarograph so close to that given by ascorbic acid that, in high concentrations, it is difficult to estimate ascorbic acid in their presence. For this reason, we have examined in detail the possibility of using formaldehyde to differentiate between them and ascorbic acid, and have found that if proper precautions are taken this reagent provides a valuable means of making the titration with 2,6-dichlorophenolindophenol a highly specific method for estimating ascorbic acid in the presence of reductone-like substances. As reliable methods for assaying ascorbic acid in dehydrated foods are of topical interest to an increasing number of workers, a preliminary note on a method so far found successful seemed appropriate.

The method used is as follows. The material to be analysed is extracted with sufficient 5 per cent metaphosphoric acid, according to the method recommended by Harris and Olliver[8], to give an extract containing preferably between 0·04 and 0·10 mgm. of ascorbic acid or its equivalent per ml. If the material to be analysed is too poor a source for this to be done, it should be extracted with the minimum of metaphosphoric acid consistent with adequate extraction. The extract should be kept in the dark during the analytical operations.

If the presence of sulphide, sulphite or sulphydryl compounds is suspected, an aliquot portion of the solution is adjusted to *p*H 0·6 by the addition of 50 per cent H_2SO, then HCHO to a concentration of 4 per cent is added and the solution titrated against indophenol dye after standing for 8 min. at 20° C. If no sulphide, sulphite or SH compounds are present, this preliminary treatment may be omitted and the first step is to titrate the metaphosphoric acid extract (*p*H 1·2) directly against indophenol. In either instance, this titre, expressed as ascorbic acid, is the initial value (A) for plotting graphically at zero time. (Modifications in the initial treatment have to be carried out if the metaphosphoric acid extract contains substances like dihydroxy maleic acid, or reducing compounds present in malt extracts or beet molasses which are unstable in metaphosphoric acid solutions ; for details the reader is referred to the fuller paper in the press.)

A further aliquot of the metaphosphoric acid extract is adjusted to *p*H 2·0 by the addition of sodium citrate solution and HCHO added to a concentration of 8 per cent, and the solution allowed to stand at 20° C. Samples of this solution are withdrawn at intervals of 5–10 min. and immediately brought to a *p*H value of 0·6 by the addition of 50 per cent H_2SO_4 in order to arrest further reaction. These several solutions are titrated against indophenol within 5 min. of taking the sample. It is quicker, and little accuracy is lost, if the samples of solution at *p*H 2·0 mixed with HCHO are titrated directly with indophenol without the addition of H_2SO_4, provided there is no delay and the time interval noted in each instance between the start of the reaction and the moment of titration.

These titrations should be carried out at intervals over a period of 0–90 min. after adding the HCHO, and the values of the indophenol titres, expressed as ascorbic acid, plotted as ordinates, against the times as abscissæ. The line joining the points on the later flat part of the curve so obtained is extrapolated back to the ordinate axis, cutting it at a point X. The difference between the initial indophenol titre A and the value represented by the point X is equivalent to the ascorbic acid content of the extract.

The principle of the procedure is as follows. In the preparatory treatment used in the presence of sulphydryl compounds, the latter are removed by condensation with the formaldehyde but, at the very acid reaction employed, ascorbic acid and reductones remain unaffected. The initial titration A, at *p*H 0·6 or 1·2, measures ascorbic acid plus reductones. In the second reaction, in the less acid solution (*p*H 2), the ascorbic acid is completely removed by condensation, while the reductones are only slowly condensed, and their amount can, therefore, be found by extrapolation in the manner described, the ascorbic acid being given by difference.

The method so applied to fresh vegetable and animal tissues, and some typical cooked foods, jams, canned foods, etc., gives results agreeing well with those obtained by the ordinary, direct indophenol titration, but in the special case of certain dehydrated foods subjected to heat treatment, the ascorbic acid values are found to be lower than those given by the simple titration with indophenol. Although, for example, the ascorbic acid content of freshly dehydrated cabbage, whether determined by direct indophenol titration, by biological test[9], or by the formaldehyde method, is identical, after the dried cabbage has been stored at temperatures in excess of 25° C., there is a gradual production of substances capable of reducing indophenol which resemble reductones in their reaction to formaldehyde. Reductones may also be produced in dehydrated foods if the fresh materials are dried at unduly high temperatures so as to cause even slight scorching of the tissues. For these reasons, it is advisable when estimating ascorbic acid in such materials, or in fermented or caramelized foodstuffs in general, to employ a method which will differentiate between it and reductones, or reductone-like substances. Full experimental details of the method, and an account of the results, will be published shortly.

APPARENT VITAMIN C IN CERTAIN FOODSTUFFS

By Dr. FRANK WOKES, JOAN G. ORGAN, JEANETTE DUNCAN AND Dr. F. C. JACOBY
'Ovaltine' Research Laboratories, King's Langley

A NUMBER of previous workers[1,2,3] have reported the occurrence of non-specific indophenol-reducing substances in certain fermented or heated foodstuffs. Investigations in our laboratories during the last two years have confirmed these earlier findings and extended them to a wider variety of materials, while showing that the interfering substances may be produced under much less drastic conditions than was previously thought possible. The term 'apparent vitamin C' is suggested as conveniently describing these substances which differ from interfering substances previously studied (such as sulphites, glutathione) in simulating vitamin C so closely in their chemical and physical properties that they cannot be distinguished from it by the assay methods which have so far been generally employed. It is probable that, in contrast with sulphites, glutathione, etc., they also resemble vitamin C closely in chemical constitution.

In 1941, during experiments on the production of vitamin C in germinating grains (wheat, barley and oats) using the dye 2 : 6-dichlorophenolindophenol to estimate ascorbic acid, it was found that the apparent vitamin C content could be considerably increased by heating the germinated grains with water containing 1 or 2 per cent of concentrated hydrochloric acid, dye titration figures becoming steadily larger as heating continued. At *p*H 4·5–5·0 in absence of mineral acid, the production of the apparent vitamin C in extracts of these grains took place equally rapidly at 100° C., and still occurred more slowly at lower temperatures down to 5 or 6° C. Its rate of production is also affected by the moisture content, being almost completely inhibited by reducing this to 1 or 2 per cent. The apparent vitamin C thus obtained resembles ascorbic acid in many of its properties, being rapidly destroyed by oxidase from cabbage leaves or tomato skins, by shaking with charcoal in air and by very low concentrations of hydrogen peroxide (1 in 10^6) or of percarbonate (1 in 10^5), but has not the physiological properties of vitamin C. It has been found in a variety of food products, including fruit syrups, cocoa, malt extract, dehydrated fruits and vegetables and cane and beet molasses; also in a number of samples of beer. Concentrated preparations have been obtained with an apparent vitamin C content of 200–300 mgm. per 100 gm., but no physiological activity as shown by biological tests. Spectroscopic examination of some of these preparations by Dr. R. A. Morton showed absorption maxima at 256–264 mμ, and 275–280 mμ, suggesting the presence of reductic acid first described by Reichstein and Oppenaeur[4] and possibly of dihydroxymaleic acid (*vide* S. Györgyi[5]) or of oxytetronic acid (*vide* Mohler and Lohr[6]). Attempts to extract dye reductants from these concentrated preparations by shaking or heating in a soxhlet with methanol or ethanol or by prolonged shaking of the aqueous extracts with ether have so far failed.

During the last two years we have experimented with various methods of estimating ascorbic acid in the presence of these non-specific dye-reducing substances, based on various properties such as their stability towards heat and instability towards acid in dilute aqueous solution. By such methods we discovered that the development of apparent vitamin C in certain foods during processing involving heat, or during storage, may lead to dye titrations giving false impressions of the vitamin content and its stability. In December 1942, learning from Dr. Mapson that he was working on a similar problem in dehydrated foods, we interchanged results with him, and at his suggestion explored the possibility of estimating true vitamin C in our experimental materials by condensation with formaldehyde as proposed by Lugg[7].

Mapson[8] has investigated the formaldehyde method thoroughly. He obtains the best results at a *p*H of about 2. However, the interfering substances with which he has been mainly working are probably of the nature of reductones such as Norrish and Griffiths[9] obtained by heating various carbohydrates with alkali. Spectroscopic evidence indicates that changes take place in reductones when *p*H is below 6. Our apparent vitamin C, which is produced at a *p*H below 5, and in some instances so low as 1, differs from reductones in being unstable in metaphosphoric acid solutions, and in being more readily distinguished from true vitamin C by condensation with formaldehyde at *p*H 4–5 than at *p*H 2. At *p*H 4–5, formaldehyde reacts with only a small fraction (usually 5–10 per cent) of the interfering substances while destroying the whole of the true ascorbic acid. The total apparent vitamin C in the preparation is first estimated by the potentiometric method of Harris, Mapson and Wang[10], particular care being taken with the precise timing and rate of addition of dye as mentioned by Wokes *et al.*[11]. The true ascorbic acid is then destroyed by six minutes treatment with 6 per cent of formaldehyde at *p*H 4–5 and room temperature, and apparent ascorbic acid again estimated. The difference between the two results, corrected for the small amount of interfering substance which has also condensed with the formaldehyde, indicates the true vitamin C content. In all determinations of apparent vitamin C the metaphosphoric acid extracts should be stabilized with nitrogen as soon as they are made. The above method has given satisfactory results with mixtures of true ascorbic acid with the interfering substances in widely different proportions, duplicates agreeing within the limits of experimental error of the potentiometric method, which we found more suitable for many of our coloured products than the visual method used by Mapson.

Apparent vitamin C has not yet been found in *fresh* fruits and vegetables, although we have reason to believe that it is not entirely absent from the vegetable kingdom. Hochberg, Melnick and Oser[12] have recently reported some interesting findings on *dried* tomatoes and potatoes which we also have been studying. Using a photometric method of estimating vitamin C in which the rate of decolorization of the dye is followed by readings taken every five seconds, they find that on storage there is progressive formation of dye-reducing substances which in visual titrations react slowly, thus giving too high results. They appear to think that this apparent vitamin C which gradually develops may contain dehydroascorbic acid as well as other non-specific dye-reductants. They claim that their method is much more specific for true ascorbic acid, allowing determinations to be made in the presence of relatively large amounts of other substances which reduce the dye. We have followed by means of E.M.F. changes the rate of reaction of true and of apparent vitamin C with the dye in many estimations during the last eighteen months, and agree that the non-specific substances reduce the dye more slowly than ascorbic acid does. In contrast with the above authors, we find the reaction of the dye with ascorbic acid to be completed in less than two seconds, even with much higher concentrations of ascorbic acid than they employed, while the reaction with dihydroxymaleic acid and other constituents of apparent vitamin C may require more than a minute for its completion. We consider this method of estimating true vitamin C in the presence of apparent vitamin C to be less accurate than the formaldehyde method, either used visually as described by Mapson or (when this is not applicable) used potentiometrically as described above.

We are indebted to Dr. L. J. Harris and his colleagues for advice and criticism, to Dr. R. A. Morton for spectroscopic examination of various samples, and to Mr. H. C. Powers, chief chemist, Messrs. Tate and Lyle's Thames Refinery, for samples of molasses.

Details of this investigation will be published elsewhere.

OBITUARIES

Prof. Charles Schuchert

THE death of Prof. Charles Schuchert, which occurred on November 20, 1942, removes an eminent American stratigrapher and palæogeographer, who was also a leading authority on brachiopods. Born at Cincinnati on July 3, 1858, he was early attracted by the richness in fossils of the rocks surrounding his home; and although he received only a primary school education, which ceased when he was fourteen, he made such good use of his opportunities of collecting that he attracted the attention of the great American palæontologists of the period. In 1885 he was given employment as assistant in palæontology to E. O. Ulrich, and later he worked in turn with James Hall and with C. E. Beecher. He worked in connexion with the Geological Survey of Minnesota, and in 1893 became assistant palæontologist to the United States Geological Survey. In 1894 he was appointed assistant curator in palæontology at the United States National Museum, where he remained for the next ten years, having opportunities during this period to collect in Europe, Greenland and Canada. In 1904, at Yale University, he became concurrently professor of palæontology, professor of historical geology in the Sheffield Scientific School, and curator of the geological collections at the Peabody Museum. He remained at Yale for the rest of his life, receiving the title of professor emeritus on his retirement in 1926, and of director emeritus of the Peabody Museum on his eightieth birthday. He received honours from various universities and learned societies; he was president of the Geological Society of America in 1922, and was elected foreign correspondent of the Geological Society of London in 1927 and foreign fellow in 1929.

Schuchert's published books, papers and articles amounted in all to between two and three hundred items, their subjects including stratigraphy and palæogeography, primarily of America, systematic palæontology, and scientific biography. His interests covered the whole geological column, but he concentrated especially on the Palæozoic. Together first with Pirrson and then with Dunbar, he published "A Text-book of Geology", being himself responsible for the section on historical geology; and in 1927 appeared a book intended for the layman, "The Earth and its Rhythms", written jointly with Clara M. LeVene.

In the field of palæontology, he worked principally on the Brachiopoda, although members of other groups, especially of the Echinodermata, also claimed his attention. About 1902, he presented his collection of fossils, including ten thousand brachiopods, to the United States National Museum, but he made a further collection of some hundred thousand specimens of brachiopods which he bequeathed to Yale.

His knowledge of the brachiopods was wide and deep. He published many papers on their systematics, including in 1932 a monograph of the Orthoidea and Pentameroidea written in collaboration with G. A. Cooper. Perhaps, however, the greatest significance of his work lies in the fact that he was the earliest author to produce a general conspectus of the group following on the pioneer work of Davidson, Hall and Clarke, and the other great 'brachiopodists' of the later nineteenth century. In 1897, Schuchert published "A Synopsis of American Fossil Brachiopoda including Bibliography and Synonymy", which has remained a standard work, containing a sound discussion of the evolution of the group. Later he undertook in Zittel-Eastman's "Text-book of Paleontology" the section on brachiopods, which again is indispensable as a work of reference. In 1929, together with Clara M. LeVene, Schuchert produced the brachiopod section of the "Fossilium Catalogus", an invaluable index of genera and genotypes, newly classified.

Schuchert's combination of detailed knowledge of the brachiopods with a wide and inclusive outlook on palæontology enabled him to recognize systematic differences but yet at the same time to avoid excessive 'splitting', while producing an orderly classification from a chaotic group. The outcome of long-continued thought and consideration, his studies revealed with complementary clarity the nature both of the component individuals and of the group as a whole.

Muriel A. Arber.

We regret to announce the following deaths:

Prof. William M. Esten, emeritus professor o bacteriology in the University of Connecticut, o April 16, aged eighty.

Dr. K. Landsteiner, For.Mem.R.S., of the Rockefeller Institute for Medical Research, on June 26, aged seventy-five.

Prof. Garfield Powell, assistant professor of chemistry in Columbia University, aged forty-nine

Dr. Mary J. Rathbun, honorary associate in zoology of the U.S. National Museum, on April 4, aged eighty-two.

Prof. W. A. Setchell, emeritus professor of botany in the University of California at Berkeley, on April 5, aged seventy-eight.

Prof. William C. Walker, professor of chemistry in McMaster University, Canada, on March 30.

NEWS and VIEWS

Industrial Research in Great Britain

Sir Edward Appleton, secretary of the Department of Scientific and Industrial Research, in opening the new physico-chemical laboratories of the British Coal Utilization Research Association at Coombe Springs on June 23, congratulated the Association both on its new facilities in laboratory space and on the financial provision now available for large-scale work. The steps the Association has taken are among the first notable signs of a great forward movement in industrial research in Great Britain, Sir Edward said, which he confidently expects will be one of the features of post-war Britain. The Coal Utilization Research Association is serving the coal industry as a whole, and he particularly welcomed the expression of the interest of the miners themselves shown in the recent appointment of two members of the Mineworkers' Federation to the council of the Association. It is, he said, fashionable nowadays to decry British industrial research effort, because it is claimed that the amount of money spent on research per head of population is less than that in certain other countries. Much depends, of course, on what basis such a calculation is founded; whether or not, for example, development costs are included under the heading of research. Moreover, there can be unwise expenditure, as well as wise expenditure, even on research. But it can certainly be stated that British effort on research is not commensurate with our industrial needs. To talk merely of spending more money, however, was not enough. It was necessary to plan our attack on both new and old problems and, most important of all, to attract some of our best scientific brains in the country to solve them.

It has also been stated that, whereas Great Britain has, in the past, been responsible for many of the most fundamental discoveries in science, other countries have often been the first to apply them to practical ends. Sir Edward said that he could safely predict that when the full story can be told after the War, our work in the application of science, as distinct from the accumulation of scientific facts, will be found second to none. He instanced the example of one of the most striking of our war-time developments, namely, that of radio-location, which was not, as is commonly supposed, a new invention. Here a technique developed for purely scientific ends has been magnificently applied by young British scientific workers to practical war-time uses. In this and other fields it has been amply demonstrated that the young men of Great Britain can hold their own in bridging the gap between laboratory science and its useful expression in appliances and industrial processes.

National Academy of Peiping

A report of the National Academy of Peiping covering the years 1937–42 has been issued by the Kunming Office of the Academy. On the outbreak of the present war with Japan, Peiping was immediately taken over by the invader, and the Academy, which at its foundation in 1929 consisted of nine separate research institutes with a staff of more than two hundred, succeeded in transferring part of the books and equipment of each of its institutes to the south; within a few months most of its work was resumed at Kunming, Yunnan, with a staff now consisting of 120 members. In addition to Chinese Government grants amounting to 620,000 dollars, grants are received from the Sino-American, Sino-British and Sino-French Foundation Funds. The Institute of Physics has been increasingly concerned with problems of industry and national defence. A laboratory for spectroscopy has been established to meet the needs of the new metallurgical industry, and the Institute has also standardized more than a thousand radio transmitters with its own quartz oscillators. Its other efforts have been confined mainly to the development of applied optics and geophysical prospecting. The Institute of Radium consists of laboratories for chemistry and radioactivity, in which many Chinese minerals have been examined, and for X-rays, where the work has been mainly on crystal analysis and X-ray studies of alloys of tungsten and antimony.

In the Institute of Chemistry, work has been carried out on the extraction of dyes from local plants and their application to textiles, the preparation and small-scale manufacture of medicinals from local raw materials, the recovery of used engine oils, replacement of Diesel oil by vegetable oil and preparation of a substitute for petrol from molasses and sawdust, analysis of water supplies and extraction of potash from different types of ashes. The Institute of

Materia Medica has concentrated on investigations of Chinese drugs, such as Chinese ephedra. The active principles have been isolated, and their properties and pharmacological action studied. Some materials such as ephedrin and vitamin B_1 have been prepared on a commercial scale for clinical use. The Institute of Physiology has extended its investigations on the physiological effects of various Chinese drugs to investigations on the nutrition values of the foodstuffs used by inhabitants of the south-west of China, and the treatment of Chicken cholera with sulphanilamide. The Institute of Zoology, besides work on the fauna of Yunnan, has made systematic studies of the principal freshwater fauna of Yunnan, particularly the fishes of the inland lakes, their diseases and enemies. The Institute of Botany has commenced investigations on economic botany, in addition to those on agriculture and forestry already in progress, and a special survey of the plant life of north-west China has been planned and organized. The Institute of Geology is mainly occupied with the detailed mapping of mineral deposits (see also p. 9 of this issue of NATURE).

Earthquake in Turkey

ON June 20, following foreshocks during the previous night to the accompaniment of torrential rain, a severe earthquake shook the beautiful, rich, fruit-growing district just to the east of the Gulf of Ismid, on either side of the Istanbul-Ankara Railway about sixty miles east of Istanbul. The epicentre of the shock was near, and probably just east of, the town of Adapazar, where most of the buildings were wholly or partly wrecked. Other towns more or less damaged in the district were Geyve, Arefie and Hendick, the latter twenty miles east of Adapazar. Nearly all the villages in the district suffered. The shock was felt severely in Istanbul, where some apprehension was caused by walls collapsing. The Constantine Pillar in old Istanbul, dating from the first half of the fourth century, is reported to have been damaged.

Adapazar is a town of some 20,000 inhabitants, and it is fortunate that most of the people there and in the surrounding districts were out of doors, otherwise the death-roll would have been higher than the present estimate of 2,000. Telephone and rail communication broke down so that full information is not yet available, but it is known that the bulk of the population is now living in tents in the fields and orchards of the district. A strong shock was recorded at Stonyhurst College Observatory, near Blackburn (Rev. J. P. Rowland, *S.J.*), at 15h. 38m. 26s., and another at 17h. 59m. 18s., both probably from the Turkish focus. The shock, therefore, probably took place about 15h. 32·8m. and the aftershock about 17h. 53·7m. Help has been sent to the stricken area from Ismid, Bolu and Istanbul, and further information from the district is awaited. The last serious earthquake in Turkey was some six months ago, though the country, particularly that part to the east of the present disturbance, has never been free from recurrent small shocks since the great Turkish earthquake of December 27, 1939 (NATURE, 145, 13; 1940).

Wellcome Research Institution

FREQUENT inquiries are being received, both from this country and abroad, with regard to the two Wellcome Museums. They are, and will continue to be, housed in the Wellcome Research Institution, 183–193 Euston Road, N.W.1. Although the Wellcome Research Institution building suffered considerable damage by enemy action, its structure was unharmed and the Museums can quickly be put into shape again as soon as labour and materials become available after the War. While some of the objects in the Wellcome Historical Medical Museum were damaged, it has been possible to replace or repair most of them. Fortunately, the specimens and other valuable material in the Wellcome Museum of Medical Science remained comparatively intact.

Both Museums are now under the directorship of Dr. S. H. Daukes. A comprehensive scheme for the Wellcome Historical Medical Museum has been prepared and will be brought to completion as speedily as possible after the cessation of hostilities. The Wellcome Medical Library, comprising more than 150,000 volumes, will also be in the same building, and suitable accommodation will be provided for research workers so that both the library and collections may be readily available. The Wellcome Museum of Medical Science—which in the past has been much used by teachers, students and those engaged in post-graduate studies—will be re-established in its entirety at the end of the War with the utmost possible speed. The large lecture hall will be fully re-equipped, including film projection apparatus, and will then be available for scientific lectures and meetings.

Local Industrial Health Advisory Councils

SHORTAGE of medical personnel makes it impossible to satisfy the need for an industrial health service at all fully at the present time in Great Britain, but in every area there are individuals who have sufficient knowledge and experience to give very material assistance in solving local problems. The workers themselves are beginning to take an active interest in measures to promote safety and health, and in some factories safety and/or health committees have already been set up. One of the difficulties that faces these committees in factories where no medical officer is available is how to obtain professional and technical advice in dealing with their problems. Advice on points to note that are particularly valuable as indications of general health trends can also be well used by interested workers. The Leicester Branch of the Socialist Medical Association has endeavoured to bridge this gap in the following way. First, a meeting of workers' representatives was called and an outline given to them of the problem as seen from the point of view of medical and allied personnel. At this meeting, considerable information was obtained regarding health conditions in local factories, and questionnaires were distributed so that further details might be submitted and collated. A second meeting was then held, this time for health workers—medical men, nurses, social workers, welfare officers, etc.—and the information received in the questionnaires was put before them. Arising out of this meeting, a local industrial health advisory council has been set up, through which it is hoped that specialist advice on industrial health matters will be available wherever it is required. There is also, of course, the Central Council for Health Education (Tavistock House, Tavistock Square, London, W.C.2), which has considerable facilities and offers help and advice on industrial and other health problems.

Astronomy in Ships' Names

A NUMBER of Victory Ships recently launched from the slips of the California Shipbuilding Corporation at Wilmington, California, have been named after astronomers. Ship No. 125 of the corporation's war-time programme, the s.s. *George E. Hale*, was launched on January 19 last after only 27 days on the ways, and commemorates the inventor of the spectroheliograph and spectrohelioscope, founder of the *Astrophysical Journal*, and constructional genius mainly responsible for the design and erection of the world's largest refracting and reflecting telescopes at Yerkes and Mt. Wilson respectively. The s.s. *Maria Mitchell*, vessel No. 147, takes her name from the professor of astronomy at Vassar College, who discovered a comet and who was the first of her sex to be elected a member of the American Academy of Arts and Sciences. Ship No. 158, the s.s. *Simon Newcomb*, launched on March 26, is named after the famous superintendent of the American Nautical Almanac Office, who was commissioned professor of mathematics in the U.S. Navy by Abraham Lincoln and who did perhaps more than any other man to popularize astronomy in the United States.

Tank-breeding Mosquitoes in Portsmouth

MR. JOHN F. MARSHALL of the British Mosquito Control Institute at Hayling Island, Hants, has recently issued a pamphlet on the above subject. It deals with the incidence of mosquitoes in static water tanks in the Portsmouth City area. Viewed as a whole, it appears that size of tank is an important factor since the occurrence of mosquito breeding becomes more and more unlikely as capacities increase above the 10,000 gallon limit. Tanks of 5,000 gallons and 10,000 gallons capacities (the two smallest employed) provided one half of the total cases of the occurrence of mosquitoes in some stage of development. In none of these examples was the water heavily infested: in all the larger tanks or sumps mosquito larvæ, when present, were few and far between. The only species of mosquitoes found breeding in the water-containers were *Culex pipiens* and *Anopheles maculipennis*, although many other kinds prevail in the district. On each occasion upon which mosquito breeding was observed, notification was sent to the National Fire Service authorities, who forthwith sprayed the infested water with oil and/or cleared it of algal growths. The success of these operations was evidenced by the fact that with only one exception no tank was found to be mosquito-infested more than once during the whole period considered (April–November).

New Zealand Earthquakes

ACCORDING to the seismological bulletin just received from the Dominion Observatory, Wellington, New Zealand, nine large earthquakes were registered during February 1943 by the seismographs at Auckland, Arapuni, Christchurch, Tuai and Wellington (Dept. of Scientific and Industrial Research, New Zealand Seismological Report, Provisional Bulletin No. P-132, February 1943, Dominion Observatory, Wellington, N.Z.). Additionally during the month twenty-seven shocks were felt in New Zealand. Three of these attained intensity VI on the modified Mercalli scale. The first, on February 17, occurred at 02h. 15·2m. U.T. and was felt in the South Island, south of Buller and Canterbury, with intensity rather greater than VI. The second on February 17, a 13h. 52m. U.T., was again felt in the southern par of South Island with intensity VI. The third on February 25 at 13h. 33·5m. U.T. was felt from Taumarunui and Napier to Hokitika and Akaroa with intensity VI. One shock had intensity V. It was on February 20 at 01h. 48·4m. U.T. and felt in the neighbourhood of Te Anau. Four shocks were felt with intensity IV and the remainder had lesser intensities.

Occultation of Venus

MR. M. A. ELLISON writes: "Permit me to correct and also to amplify the statement of planetary conjunctions given under 'The Night Sky in July' in NATURE of June 26, p. 724. These are described both as conjunctions and as occultations: in fact it is only the conjunction of Venus which leads to an occultation visible in the British Isles. This daylight occultation (disappearance July 6 at 15h. 45m. for Greenwich) is of special interest by reason of the great brilliancy of the planet, which should render it an object easily visible to the unaided eye. The moon will be slightly west of the meridian at an altitude of about 50°. There follows, within half an hour, the occultation of α Leonis, a double event observable with a 2-in. telescope".

Announcements

IF circumstances permit, the Trustees of the Lady Tata Memorial Fund will make the following awards for research in blood diseases, with special reference to leukæmia, in the academic year beginning on October 1: *Grants for research expenses:* Dr. J. Furth (New York); Dr. P. A. Gorer (London); Dr. A. H. T. Robb-Smith (Oxford); Prof. L. Doljanski (Jerusalem). *Part-time personal grant and grants for assistance and research expenses:* Dr. W. Jacobson (Cambridge).

THE following appointments and promotions have recently been made in the Colonial Service: G. A. Walton to be medical entomologist, Sierra Leone; E. Lawrence, agricultural officer, Nyasaland, to be senior agricultural officer, Nyasaland; W. E. Calton, laboratory assistant, Tanganyika Territory, to be assistant Government analyst, Tanganyika Territory; G. S. Brown, L. F. Higgens, L. Leslie Moore and W. S. Warne, agricultural assistants, Tanganyika Territory, to be senior agricultural assistants, Tanganyika Territory.

"RECOGNITION of Decay and Insect Damage in Timbers for Aircraft and other Purposes" is the title of a bulletin issued by the Department of Scientific and Industrial Research. It deals in the main with information for the use of timber inspectors and lists certain timbers in general use, with notes on their resistance to insect attack and decay. In its eighteen pages it deals with those defects and blemishes which occur most commonly in woods ordinarily used in the construction of aircraft and airscrews. The present shortage of timber has made it important to use it economically, and home-grown woods have been called on to make good the diminution of imports. The pamphlet is obtainable from H.M. Stationery Office or through any bookseller, price 6*d*. net.

Thermal Scattering of X-Rays by Crystals

THE influence of the thermal vibrations on the diffraction of X-rays by a crystal can be represented by a distribution of scattering power in the reciprocal lattice. The theoretical formula for this is the product of two parts: one, consisting of slowly varying factors which correspond to the atomic scattering factor, the polarization factor, Debye's temperature factor, the Lorentz factor, of Laue-Bragg scattering; the other part consisting of a function characteristic of the dynamics of the crystal vibrations, the diffusion factor $d(Q)$. For a simple lattice the latter has the form

$$d(Q) = \sum_{\alpha,\beta=1}^{3} S_{\alpha\beta}(Q) Q_\alpha Q_\beta, \quad . \quad . \quad (1)$$

where Q_1, Q_2, Q_3 are the co-ordinates in the reciprocal lattice, and $S_{\alpha\beta}(Q)$ are the elements of the scattering matrix S, periodic functions of the Q. S can be expressed as a function of the dynamical matrix D, which is defined in terms of the coefficient matrix of the second order terms of the potential energy of the lattice. At normal temperatures one has, with a high degree of accuracy,

$$S = kTD^{-1}. \quad . \quad . \quad . \quad . \quad (2)$$

The elements of $D(Q)$ have zeros in the reciprocal lattice points, hence those of $S(Q)$ have sharp peaks there. In the neighbourhood of these, they can be expressed in terms of the elastic constants of the crystal. In this way Jahn has calculated[1] surfaces of isodiffusion for sodium, and Mrs. Lonsdale and Mr. Smith have shown[2] that the results are in good agreement with observations.

Since the experiments show, for many materials, a definite structure of scattering power ('streamers' or 'bridges') in the space between the lattice points, it seemed desirable to have a method of calculating the matrix $S(Q)$ for any point of the reciprocal space. This can be done in two ways: either by using numerical calculations of the matrix D as published by Iona[3] for potassium chloride, and by Kellermann[4] for sodium chloride, or by using a crystal model for which D can be theoretically constructed. We have applied both methods. But as Iona's tables are rather rough, containing only four points on each edge of the elementary cube in the Q-space, the resulting figure for $d(Q)$ does not show much interesting detail; it is not worth while reproducing it here.

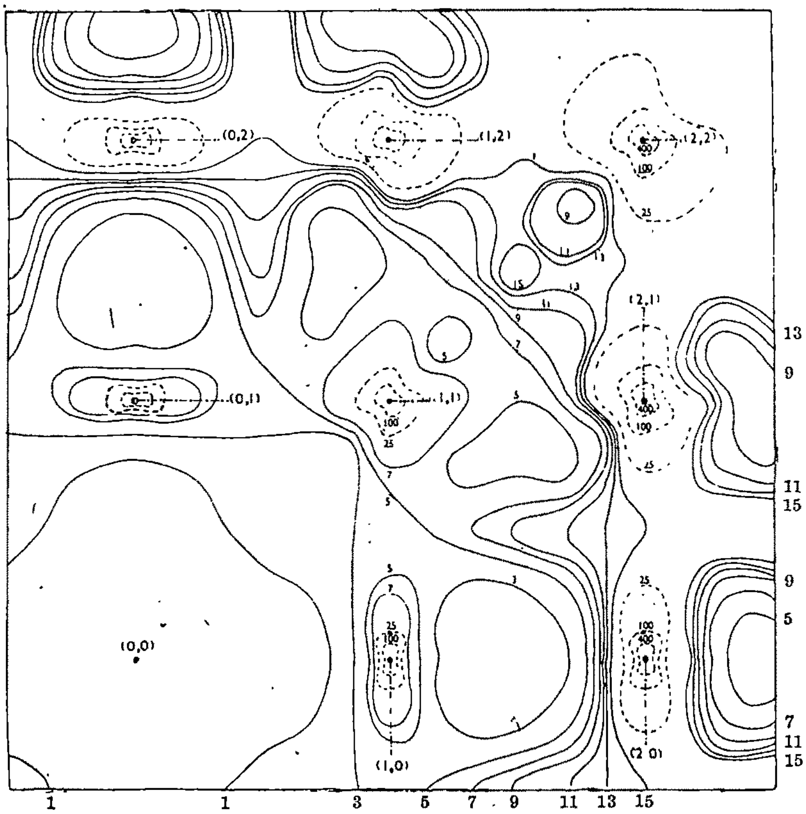
We have therefore developed the second method, taking as the model a face-centred cubic lattice in which only next neighbours act on one another, but with non-central forces. It can be shown that in this case there are exactly three force constants, which can be expressed in terms of the three elastic constants c_{11}, c_{12}, c_{44}. The typical elements of D are

$$D_{11} = (2c_{44} - c_{11})(1 - \cos Q_2 \cos Q_3) + c_{11}(2 - \cos Q_1 \cos Q_2 - \cos Q_1 \cos Q_3),$$

$$D_{23} = (c_{12} + c_{44}) \sin Q_2 \sin Q_3,$$

which for small Q go over, of course, into the expressions used by Jahn. We have in particular considered the plane $Q_3 = 0$, for which case it is not too tedious to form the reciprocal matrix D^{-1}.

In order to compare the results with the first method mentioned above, we took the constants c_{11}, c_{12}, c_{44} as those of potassium chloride, although this lattice is neither monatomic nor simple face-centred. Calculations for metallic crystals satisfying these conditions will be performed later.



Potassium chloride isodiffusion lines in the plane $Q_3 = 0$ of the reciprocal space (Q_1, Q_2, Q_3). The figures attached to the lines are the values of $d(Q)/kT$ if the elastic constants are made dimensionless by dividing them by $e^2/a^4 = 2{\cdot}40 \times 10^{11}$ dyne cm.$^{-2}$ (e is charge of the electron, a is lattice constant, 3·14 A.). The bracketed figures are the indices of the reciprocal lattice points, referred to crystal axes the lengths of which are one half those of the face-centred unit cell.

We computed the elements of D^{-1} and from this the diffusion function (1) for a sufficiently fine network of points. With the help of graphical interpolation, curves of isodiffusion were constructed which are given in the accompanying figure. This comprises nine reciprocal lattice points including the origin (marked by dots). In the vicinity of each of these (except the origin) one recognizes contours of the type found by Jahn. But one sees that the background has a definite and complicated structure; for example, secondary maxima (labelled 15). A remarkable feature is the existence of isodiffusion lines (intensities of 3 and 15, in our scale), forming almost squares which separate the whole field into unconnected sections. We hope that figures of this kind will provide additional evidence for the thermal theory of X-ray scattering.

G. H. BEGBIE.
M. BORN.

Department of Mathematical Physics,
University of Edinburgh.

[1] Jahn, H. A., *Proc. Roy. Soc.*, A, **178**, 320; **180**, 476 (1942).

[2] Lonsdale, K., and Smith, H., NATURE, **148**, 628 (1941); **149**, 21 (1942). Jahn, H. A., and Lonsdale, K., *Phys. Rev.*, **61**, 375 (1942). Lonsdale, K., *Proc. Phys. Soc.*, **54**, 335 (1942).

[3] Iona, M., *Phys. Rev.*, **60**, 822 (1942).

[4] Kellermann, W., *Phil. Trans. Roy. Soc.*, A, **238**, 513 (1940).

IN a recent lecture-survey given to the Physical Society[1] it was shown that calculations based on the Faxén-Waller theory gave good agreement with experiment, not only within the regions to which that theory could properly be applied, but also in the short wave-length range where its validity was open to question. Thus diagrams showing the observed scattering power of KCl and Na in reciprocal space and the scattering power calculated by means of Jahn's formula were in general agreement not only in the neighbourhood of the reciprocal lattice points (region of long waves) but also at a distance from those points.

Prof. Born and Mr. Begbie have now extended the calculation for the special case of a monatomic face-centred cubic model having the same elastic constants as potassium chloride, and a lattice constant equal to one half that of the face-centred unit cell of potassium chloride. They have determined the scattering power over the whole of the reciprocal lattice network which includes the origin and the first five $\{hk0\}$ reflexions (together with other reciprocal lattice points derived from these by symmetry operations), and their published diagram shows that contours of the Jahn type do indeed account for very much of the diffuse scattering.

Although it is scarcely fair to compare the isodiffusion curves calculated for a simple face-centred cubic model with the experimental results for potassium chloride crystals, which may more truly be regarded as simple cubic, yet Born and Begbie's diagram possesses features which are apparently typical of the observed data for both potassium and sodium chloride. For example, Laval's ionization spectrometer measurements[2], which showed that the 200 and 220 domains ((1,0) and (1,1) in the above diagram) were completely surrounded by regions of weak scattering, but that between 400 and 420 ((2,0) and (2,1)) and still more between 600 and 620, there were 'bridges' of strong scattering, are now seen to be consistent with the theoretical predictions. It may be of interest to mention that the observed value of the scattering power at the middle of the 600–620 bridge is about 3·4 times the minimum scattering power appropriate to this angle, Compton scattering being subtracted from both observed figures. Inclusive of Compton scattering, the ratio is about 2·2 : 1.

Born and Begbie have commented upon the appearance of isodiffusion lines forming squares the sides of which are parallel to [100] [010]. Almost equally striking are the presence of other lines parallel to the diagonals [110] [$1\bar{1}0$]. 'Bridges' of both these kinds are clearly to be seen on the beautiful monochromatic photograph of sodium chloride published by Gregg and Gingrich[3].

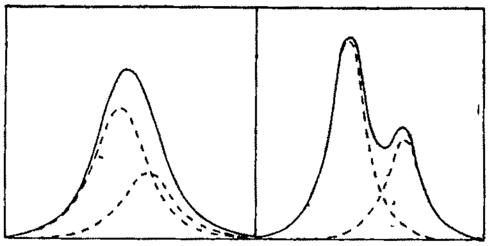
New X-Ray Evidence of the Nature of the Structural Changes in Cold-worked Metals

IN a recent issue of NATURE[1] W. A. Wood has published two interesting back-reflexion photographs from cold-worked steel, taken in the course of experiments to determine the nature of the deformation that causes the broadening of the X-ray lines. Such broadening may be caused both by the breakdown of the metallic grains into smaller crystallites and by variation of the lattice parameter from point to point in each crystal grain.

Dr. Wood compares the high-angle reflexions of molybdenum $K\alpha$ (0·7 A.) and cobalt $K\alpha$ (1·8 A.). In the former case the α-doublet is clearly resolved and in the latter it is not; Dr. Wood claims that this is a criterion which definitely shows that small crystallite size is the major cause of line broadening. Many factors, however, contribute to the broadening, and we consider that if they are all taken into account in this case the evidence is not so conclusive as Dr. Wood claims.

The two photographs show (1) line 10 (3 1 0) with cobalt $K\alpha$ radiation ($\lambda = 1\cdot79$ A., $\theta = 81\cdot1°$); (2) line 62 (7 3 2 and 6 5 1) with molybdenum $K\alpha$ radiation ($\lambda = 0\cdot71$ A., $\theta = 77\cdot7°$). (The θ values are those for a pure carbon steel; Dr. Wood does not give the composition of his specimen, but the angles are not likely to vary greatly.) In comparing these two photographs it must be borne in mind that (*a*) the breadths of the molybdenum lines will be less by a factor of 2/3 because of the lower Bragg angle; (*b*) the relative separation of the molybdenum $K\alpha$ doublet is three times that of the cobalt $K\alpha$ doublet, and this leads to a ratio of two in the actual separation on the films.



Cobalt radiation
Breadth of each component = 3·7 mm.; α-doublet separation = 1·76 mm.

Molybdenum radiation
Breadth of each component = 2·24 mm.; α-doublet separation = 2·48 mm.

Fig. 1.

We have attempted to assess the effects of these two factors in the case of lattice-parameter variation by taking hypothetical lines of average shape[2] at the respective Bragg angles, broadened in accordance with factor (*a*). The two components of the doublets are then added to give the shapes of the lines that would be observed. In Fig. 1 are shown the separate components (dotted lines) and the resultants (full lines) for the two radiations. It will be seen that

Specimen and radiation	Breadth (mm.)	Doublet separation (mm.)	Corrected breadth (mm.)	β (mm.)	θ	$\lambda R/\beta\cos\theta$ (cm.)	$\beta\cot\theta/R$
Cold-worked, Co	3·64	1·26	3·17	2·70	81·1°	$1 \cdot 93 \times 10^{-6}$	0·0094
Annealed, Co	1·31		0·88				
Cold-worked, Mo	3·25	2·48	2·24	1·84	77·7°	$0 \cdot 82 \times 10^{-6}$	0·0089
Annealed, Mo	1·04		0·69				

or cobalt $K\alpha$ one broad line is formed, but for molybdenum $K\alpha$ there are still two resolved lines; we doubt whether the difference between this result and the one that Dr. Wood shows photographically can be distinguished by eye.

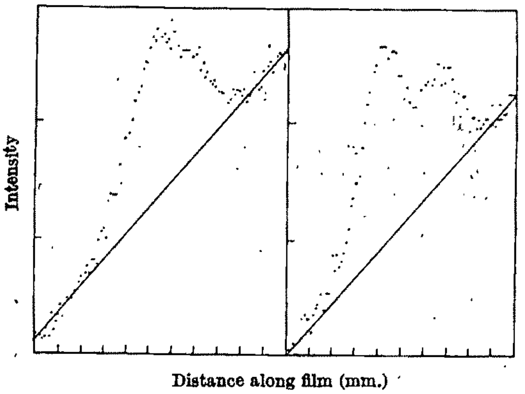


Fig. 2.

In order to examine the effect experimentally, we have taken X-ray photographs of iron filings in a camera of radius (R) 4·5 cm. with molybdenum $K\alpha$ and cobalt $K\alpha$ radiations and have made measurements on the highest spectra in each case. Photometer curves were obtained for both cold-worked and annealed filings. The curves for the former are shown in Fig. 2, and it will be seen that they resemble the hypothetical curves of Fig. 1 if allowance is made for the sloping background.

The data from the sharp lines given by the annealed filings were used to derive the diffraction broadenings, β, by the methods due to Jones[2]. The results are given in the accompanying table. The penultimate column gives the apparent particle size; the last column gives the apparent lattice distortion[3]. It will be seen that the latter is much more nearly constant than the former. Thus despite the extra visual sharpness of the molybdenum lines the detailed analysis shows that in this case the broadening is due mainly to lattice-parameter variation.

We have thought it advisable to use filings for these preliminary experiments since we are more familiar with the methods of analysing the results. The accuracy of these methods is greater than appears to be generally realized; it is definitely capable of distinguishing between broadenings proportional to sec θ and tan θ, even in line 3 of cold-worked copper. This was shown in a recent note from this laboratory[3]. An examination of the table that accompanied this note will show that if the broadening were due to small crystallite size, β should be of the order of 0·6 mm. at low angles. Since the total breadth of line 3 is only 0·64 mm., the diffraction broadening could scarcely be so great as this even if the methods of analysis were much less accurate than we suppose. We realize, however, that the nature of plastic deformation may be different in massive metal and in filings and we hope to perform further experiments, more closely resembling Dr. Wood's, to see if there is any difference in the two cases.

Value of the *p*F Scale of Soil Moisture for Expressing the Soil Moisture Relations of Wireworms

Subklew[1] and Woodworth[2] have shown that the cuticle of wireworms, Agriotes spp. and Limonius spp., is freely permeable to water, and the latter author also that it is permeable to arsenite ions. These findings have been corroborated and extended at Rothamsted, to show that when immersed in solutions of sucrose of varying concentration, anæsthetized wireworms (anæsthetized to prevent drinking and excretion) behave as an osmotic system bounded by a semi-permeable membrane.

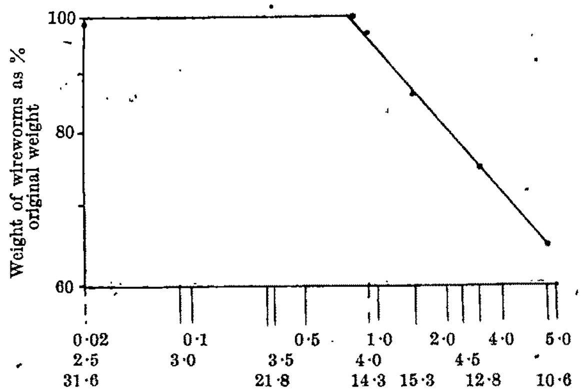
Concentration of sucrose ..	0·00	0·15	0·30	0·45	0·60	0·75	1·00*M*.
Osmotic pressure in atmospheres	0	3·80	7·54	11·34	15·27	19·35	26·42
Vapour pressure depression (per cent) ..	0	0·28	0·56	0·85	1·14	1·45	1·98
Weight of wireworm after 4 days as per cent original weight ..	122·5	116·3	102·3	91·5	85·2	82·9	80·6

These observations show that had the wireworms been placed in a 0·33*M* sucrose solution they would not have changed in weight. This solution has a vapour pressure of about 99·4 per cent or a vapour pressure depression of 0·6 per cent.

Observations were also made on normal wireworms kept in samples of a rich loam soil at a series of moisture contents. The vapour pressure depressions of the various moisture contents were determined by the methods given by Schofield and Botelho da Costa[3] and Davidson and Schofield[4].

The accompanying graph is a log/log plot of the weight of the wireworms after seven weeks (original weight taken as 100) against the vapour pressure depression of the soil sample in which they were placed. When the depression is less than about 0·6 per cent the wireworms show no consistent change in weight, intake of water through the cuticle being balanced by excretion. When it exceeds 0·6 per cent,

R282



Abscissa (top): Vapour pressure depression (%).
,, (middle): pF.
,, (bottom): Moisture (%).

water is lost chiefly through the cuticle, there being little or no excretion. In the drier soils the vapour pressure depression is due mainly to the 'suction' of the soil moisture, that is, to the fact that the water retained in the soil pores has a pressure less than that of atmospheric pressure. A suction of eight atmospheres produces a depression of 0·6 per cent. Adopting the scale proposed by Schofield, in which pF represents the logarithm of the height in centimetres of a column of water corresponding to the suction, we can say that the wireworms were in moisture equilibrium with the soil at pF 3·9.

Further experiments with other soils have confirmed that the rate of loss of water is governed by the 'suction' and not by the moisture content of the soil.

Type of soil	% Moisture content at pF 5·0	Weight of wireworms after 5 weeks as % original wt.
Woburn Sandy ..	4·03	56·7
Rothamsted allotment ..	7·52	55·9
Rich loam	10·38	56·9
	pF at a moisture content of 10·38	
Rothamsted allotment ..	4·1	86·9
Woburn Sandy	3·6	102·2

It is quite clear that the pF scale suitably expresses the dryness or wetness of a soil in relation to the loss of weight of wireworms, and should prove of value in studies of a similar kind.

Effect of *p*-Aminobenzoic Acid on Defective Cultures of Bacteria

IT has been shown by C. E. Cahn-Bronner[1] that the phenomenon of bacterial zones can be produced by partial starvation.

Some aerobic bacteria and yeasts were found to grow in a layer under the surface of the fluid culture with increasing starvation such organisms were mo sensitive to oxygen, which had a mildly bacteriostat effect on them.

This phenomenon of sensitivity to oxygen is d to lack of easily oxidizable substances, mainly carb hydrates, in the medium (acting as oxygen acceptors This type of growth is also observed in cultures *B. subtilis* grown on semi-synthetic medium co taining hydrolysed casein. Strains of *B. subtil* grown on digest broth produce a normal growth aft 24 hours in the form of diffuse turbidity and a pellicl on the surface of the medium, whereas on the syn thetic medium described by Leonard and Holme with 0·1 per cent acid-hydrolysed casein instead proteose peptone, there was weak growth in the for of slight turbidity in the deeper layers of the cultu after 24 hours but no pellicle on the surface. I absence of hydrolysed casein, growth was still les noticeable, and it was several days before the turbidit was sufficient to be estimated. Surface growth wit normal pellicle formation occurred when *p*-amin benzoic acid was added to the medium in a con centration of 1 : 2,500 to 1 : 1,100,000. In absence o hydrolysed casein, however, surface growth did no take place within 24 hours.

The addition of 4 per cent human serum to th synthetic medium had the same effect as the addition of *p*-aminobenzoic acid (and hydrolysed casein) Addition of sulphonamide compounds having anti bacterial properties in dilutions up to 1 : 100,00 inhibited the surface growth-promoting effect o *p*-aminobenzoic acid in the synthetic medium. Thi probably explains Mandelbaum's observation o bacterial asthenia[3].

Another example of defective growth under th influence of sulphonamide drugs is shown by culture of *Ps. pyocyanea* in synthetic medium, in which no only is there scanty pellicle formation but also deficiency of pigment formation over a period o 24 hours when sulphonamides are added in dilution from 1 : 5,000 to 1 : 50,000. *p*-Aminobenzoic aci antagonized the adverse effect of the compounds i dilutions up to 1 : 50,000.

Archæology as a Science

THE antithesis between history and science as central disciplines in "education for citizenship" can be resolved by making history more archæological and recognizing that archæology is a science. Mr. Hansel's just complaint[1] that "the humanities specialize in inhumanity—instruction in the accumulated evil, strife and intrigue of the ages" does not apply to prehistory, which is exclusively archæological—and archæology does not stop short when written history begins. For archæology, evil is not cumulative—one might be tempted to say, is what is not cumulative. In the archæological record (in a

Mesopotamian *tell*, for example) the destruction wrought by strife is overshadowed by reconstruction. What archæology reveals is precisely "the progress of mankind—of art, science and industry" from the painted caves of mammoth-hunters not only to the early cities of Sumer and Crete but also right down to Manhattan and Magnitogorsk. Flint axes and rotary querns, the history of which is provided by archæology alone, are just as much embodiments of science as the cyclotron. The cowrie shells from the Mediterranean adorning a Cro-Magnon skeleton in central France 30,000 years ago and the seals imported from India to Ur 4,500 years ago are just as reliable indexes of intercourse (and so of the pooling of ideas) as Board of Trade lists.

On the other hand, the methods of archæology—accurate and dispassionate observation, systematic comparison and classification, the continual reference of explanatory generalizations to the concrete data derived from observation—are truly scientific. An archæological excavation is an experiment, albeit an experiment that can never be repeated; it should be resorted to, as Collingwood insisted, primarily to test a hypothesis. Archæologists also find out by experiment how pigmy flints were made, how pots were coloured and how the ramparts of forts were 'vitrified'[2].

Prehistoric archæology at least may be deemed to have become a science in 1859. In that year Evans and Prestwich, by confirming Boucher de Perthe's claims as to the antiquity of his artefacts from the Somme gravels, vindicated the existence of pleistocene man; and Darwin, by winning acceptance for the view of man as part of Nature, not only made human history a continuation of natural history, but also gave Nature a history as well as man (as Millar so ably insists in "Science and History"). The methods of prehistory have, especially during the last twenty-five years, been increasingly applied to the study of historical periods too. Hence a lesson in archæology, even if it consist only in the comparison and classification of rusty bolts and broken tobacco-pipes from a town rubbish pit, could be at once a lesson in science and a lesson in history. But not only should it be "more stimulating and elevating", but also more interesting and easier to understand than lists of kings and battles, persecutions and proscriptions.

The corollaries would be, on one hand a more generous treatment of archæology by the State and local authorities, on the other a fuller recognition of the subject's scientific status by universities and institutions. More space, more staff and better equipment are required if existing archæological collections are to be made genuinely educational. In Scandinavia, Czechoslovakia and the U.S.S.R., I have been almost embarrassed by the streams of school classes being taken through museums by their teachers; in few museums in Britain are the archæological galleries large enough or the exhibits so arranged as to encourage this procedure. Funds are needed for further excavations not only to enlarge collections and provide sites for educational visits, but also and more seriously to recover the context within which dead monuments and relics can come to life. A more prominent position might be given to archæology in university curricula even where archæological departments already exist; for the universities must provide the teachers of archæological history and are best fitted, to direct research and experiments that cannot be repeated. Finally, the contacts between archæologists and (as I should like to put it) the other men of science might be made closer than they are and given formal recognition.

Fortieth Anniversary of the University of Peiping

THE first volume of a book commemorating the fortieth anniversary of the foundation of the University of Peiping was recently published here. The distribution was to have been from Shanghai, but owing to war conditions it is doubtful if any copies were ever sent out. The following is a list of the papers contributed to the volume.

Chang Hsi-Chih: "Observations on the Geological Structural Features in Western Yunnan".

Chang Hsi-Chih and Y. C. Sun: "New Graptolite Faunas from Lientan, Kwangtung".

Lu Yen-Hao: "Ontogeny of *Ptychoparia Szechuanensis* Sun".

Y. C. Sun: "On the Occurrence of Fengshanian (late Upper Cambrian) Trilobite Faunas in Western Yunnan".

Y. C. Sun: "The Uppermost Permian Ammonoids from Kwangsi and their Stratigraphical Significance".

H. C. T'an: "Preliminary Report on the Geology of the Tzuhsing Coal Field in Southern Hunan".

H. C. Wang: "Geology of the Kunming Region".

Yung Chung-Chien: "Preliminary Notes on the Lufeng Saurischian Remains".

Yueh-Chiang Chen: "Notes on some Freshwater Amphipods of Peiping".

Man-Chiang Niu: "The Anatomy of a Salamander, *Triturus Orientalis* (David)".

Man-Chiang Niu: "A Comparative Study of the Skeletons of *Ophiocephalus argus cantor* (Ophiocephalidæ) and *Parasilurus asotus* L. (Siluridæ) with those of *Carassius auratus* L. and *Ctenopharyngodon idellus* C. and V. (Cyprinidæ)".

Chia-Tui Shen: "The Larval Development of Some Peiping Caridea—Caridina (Atyidæ), Palæmonetes and Palæmon (Palæmonidæ).

H. C. Yin: "Effect of Auxin on the Pigment-content, Respiration, and Photosynthesis of *Chlorella vulgaris*".

T. L. Woo: "Anthropologische Studien über die Chinesische Patella".

Wentworth Chu and Chung-Kwei Chang: "Transients of Resistance-terminated Dissipative Band-Pass Electric Wave Filters".

Edith Ju-Hwa Chu: "A Modified Procedure for Preparing *o*-Bromobenzoic Acid".

S. L. Chien and Y. F. Sui: "The Dipole Moment of 2,2′, 4,4-Tetranitrodiphenyl".

If any scientific workers in Britain or America would like to receive copies of any of these papers, we can arrange to send them in typewritten or mimeographed form. Requests should be addressed through Dr. J. Needham, via the British Council, 3 Hanover Street, London, W.1.

RESEARCH ITEMS

Origin Myth of the Acoma Pueblo Indians

M. W. STIRLING has brought together all the available information in regard to the origin myth of Acoma (Bur. Amer. Ethnol., Smithsonian Inst., Bull. 135). It seems to be a psychological fact that all thinking peoples like to evolve a creation legend for themselves or to borrow one already in existence. The primordial cow licking a lump of salt in Norse legends and the Babylonian account of the creation of the world, of which the first chapter of Genesis is but a spiritualized version, at once come to mind. Humanity has always been interested in origins, and it likes the start of things to be as simple as possible. Even stories of natural phenomena tend to become simplified into a single account. Thus we find deluge legends almost universally. These generally differ entirely in form, and there is no reason to trace any cultural connexion between them. At the same time, the workings of the human mind are extremely interesting, and the various fundamental legends excogitated by folk in different parts of the world are necessarily of great importance. In the case of the Acoma, everything started with two women who were born underground (how is not stated) at a place called Shipapu. There was also a creative spirit called Tsichtinako who acted as their guardian, brought them to the surface of the ground, gave them images of animals and plants, and showed them how to give these life and how to distribute them to the various points of the compass. Of course in due time human beings were given life, this time apparently through the fertilizing of the women by Tsichtinako himself, and were taught various taboos and ceremonies. All these happenings are reproduced in play-acting when various ceremonies take place during which a ladder is mounted to represent the emergence of the two women from the depths of the earth—the ladder is supposed to represent the rainbow, by the way—and elaborate hunting and other scenes occur, considered to reproduce the instructions given by Tsichtinako. There is also a spirit of evil, as well as what seem to be guardian spirits. These, too, appear in the ceremonies. The 114 pages of the Bulletin—with many full-page illustrations, one in colour—repay careful perusal.

Noctuid Moths at Light Traps in America

H. H. WALKDEN and D. B. Whelan discuss the trapping of owlet moths (Phalœnidæ or Noctuidæ) by means of light in Kansas and Nebraska in Circular No. 643 of the U.S. Department of Agriculture (Nov. 1942). By the use of light traps located at six widely separated points in the Missouri Basin, information was obtained regarding the seasonal occurrence and abundance of a group of moths containing many notoriously injurious pests. During a four-year period (1934–37) 305 species of these moths were captured, totalling more than 525,000 individuals. About 90 per cent of the specimens taken were species of economic significance. More than 36,000 individuals were examined for sex, and it was found that 35 per cent were females but that the sex ratio varied greatly with the species. The number of moths taken differed greatly in the different localities and also from year to year. In general, flights of individual species showed the same trend in all the localities. Species having a single annual generation had rather a short flight period, usually from late August until early October. *Chorizagrotis auxiliaris*, however, had an enormou flight in May and June, followed by a much lighte flight in the fall. Owing to the overlapping of brood the flights of different generations of multiple generation species were not clearly defined. It i considered that the data obtained are basic to, or o value in, the consideration of cultural control an other methods for the suppression of the variou pests involved. Although the response to light varie with different species, it is probable that the numbe of individuals recorded is a fairly reliable estimate o the relative abundance of the species in the area concerned.

Studies in Siricidæ or Wood-wasps

R. B. BENSON has discussed the members of thi family that occur more especially in Europe and southern Asia (*Bull. Entomol. Res.*, **34**, 27 ; 1943). Included in his paper is also a key to the genera of the world. The two subfamilies Siricinæ and Tremecinæ are taken to be valid groupings that are supported by biological differences. So far as is known the former are wholly associated with conifers and the latter with angiospermous trees. Two ratios are introduced as characters for specific differentiation, namely, the ovipositor/fore-wing ratio and the sawsheath/ovipositor ratio. These ratios were found to hold good in all the specimens in the British Museum collection and, furthermore, were found not to vary with the size of the insects. In dealing with the British members of the Siricidæ it is suggested that *Urocerus gigas* subsp. *taiganus* nov. and the form of *Sirex juvencus* Ll. with entirely black antennæ may be native in the Caledonian forest. The extinct family of the Pseudosiricidæ, the remains of which are common in the Upper Jurassic strata of Bavaria, is remarkably similar to the Siricidæ but the cross-veins in the fore-wings are greatly reduced. Since it is unlikely that these cross-veins, after having become lost in the Jurassic Pseudosiricidæ, should have been regained in modern sawflies it is considered that the first-named group could not have been ancestral to the Siricidæ as believed by some workers. The paper concludes with a list and short discussion of the Oriental and Himalayan Siricidæ.

A New Source of Pectin

PRACTICAL importance may be attached to the discovery, reported by T. P. Ghose and S. Krishna in *Indian Forest Leaflet* No. 23, 1942, from the Fores Research Institute, Dehra Dun, that the seeds o *Tamarindus indica* contain a very high proportion o pectin (some 58 per cent of the kernel being obtained as a crude alcohol precipitate). The tamarind is cultivated throughout India, Burma and Ceylon, mainly for the sour fruit, an enormous quantity of which i consumed ; at present the seeds are usually thrown away, so that if arrangements can be made for thei retention and collection a low-priced source of pecti should be available and one which permits readil of storage and transport until such time as it is convenient to extract the pectin. Particulars are give of a method of extraction and isolation of the pectin which readily forms a firm jelly with suitable proportions of sugar and citric acid.

Fruit Production

M. B. Crane and A. G. Brown (*J. Genet.*, **44**, 160 1942) show that in some varieties of plums pollination with different varieties gave various difference in the time of maturity and in the size of the fruit. The pollen influences the fruit in so much as defective embryos give rise to earlier ripening and smaller fruits. The developmental differences in the fruit are an expression of different degrees of seed developments. Thus seedless fruits from diploid × hexaploid ripen first, seeded fruits of $2X \times 4X$ ripen next, and $2X \times 2X$ ripen last. These authors and D. Lewis (*J. Pomol.*, **20**, 40; 1942) point out that seedless fruits of Fertility and Conference pears have been obtained after frost treatment.

Deep-Focus Earthquakes and Aftershocks

Ross R. Heinrich discusses this question in connexion with the earthquakes which centred near the Ecuador-Colombia border during May, June and July, 1942 (*Earthquake Notes*, 14, Nos. 1 and 2; 1942). This series apparently began with a very violent shock on May 14, 1942, at 2h. 14m. U.T. and ended with a widely recorded shock on July 12, 1942, at 5h. 06m. U.T. Examination of the data so far received by the Central Station of the Jesuit Seismological Association, and of the St. Louis, Florissant, Cape Girardeau and Little Rock seismograms reveals difficulties in the interpretation of S and the determination of the depth of focus. This is not unknown in the case of earthquakes in the same region. The S phase is characterized by an emersio followed at a fair interval by an impulse of considerable magnitude. The interval and general character of the e and i vary on different components and instruments. Moreover, in the distance range of the North American stations the S phase is preceded by PS, and this adds further to the confusion of the interpretation. The strength of the preliminary phases as compared with the surface waves would suggest deep-focus earthquakes, and this interpretation agrees with the macroseismic evidence. However, pP and sS are difficult to discern though at St. Louis the $(sS-S)/(pP-P)$ ratio suggests a focal depth in the region of 500 km. If the above interpretation is correct, this swarm should furnish some interesting data on deep-focus earthquakes, but whatever the final analysis, it seems evident that these earthquakes are genetically associated.

Tuberculin Proteins

F. B. Siebert and J. W. Nelson (*J. Amer. Chem. Soc.*, **65**, 272; 1943) have shown that tuberculin contains at least two protein components which can be distinguished by different mobilities in electrophoresis. The molecular weights appear to be about 32,000 for the slower and about 16,000 for the faster. Both have immunological specificity, but the larger one is more potent as a tuberculin and more antigenic. The smaller molecule may elicit antibodies which appear with the faster serum components, α-globulin or even albumin.

Acyl Migration in Steroids

A remarkably facile acyl migration, so far without analogy in the steroid series, has been found by V. A. Petrow, O. Rosenheim and W. W. Starling (*J. Chem. Soc.*, 135; 1943) to occur in the monoesters of *cis*-Δ^5-cholestene-3 : 4-diol. The 3- and 4-monoesters were prepared by methods described, a new and elegant method being used for the preparation of the 4-esters from cholesterol. An acyl migration from C_3 to C_4 occurs on warming the 3-monoacetate of the *cis*-diol in acetic acid solution, the reaction being reversible, and another example was found in the successive substitution of chlorine for hydroxyl and hydroxyl for chlorine at C_4 in 3-acetoxy-Δ^5-cholesten-4-ol. An intermediate formation of orthocarbonic esters, analogous to that occurring in acyl derivatives of glycerol and carbohydrates, is suggested as an explanation of the reaction, but an alternative mechanism involving a transannular tautomerism is also discussed.

Welding of Cast Iron

The welding of broken or worn iron castings is reviewed by J. G. Pearce (*Quart. Trans. Inst. Welding*; Oct. 1942), and a preliminary report of some experimental work on the same subject by W. J. Driscoll appears in the same publication. It is shown that welding can be successfully applied to a wide range of repair work more cheaply and expeditiously than by replacing the casting itself. The most popular process is by bronze welding, which is the only one available for malleable cast iron. When employing this method, little preheating is required, and since the fusion temperature of the bronze is well below that of the cast iron, there is less risk of cracking or distortion. The weld is but little weaker than the parent casting and is easily machined. The main disadvantages of this process are that the weld is unsuited to service at elevated temperatures, and that the penetration is not great. Using a fusion method there is much better penetration, and, especially in the case of oxy-acetylene welding, good strength. The higher temperatures involved in the welding result, however, in a greatly increased risk of distortion and possibly even of the cracking of the casting under repair.

Solar Prominences and Sunspots in 1937

Observations of solar prominences for 1937 were conducted at the University of Valencia with the equatorial Zeiss, aperture 15 cm. and focal length 2·2 metres; a spectroscope which was previously at the Observatorio Astronómico de Madrid was adapted to the Zeiss for prominence work (*Bol. Ast. Observ. Madrid*, **2**, No. 8; 1942). The first part supplies the usual information on prominences, date and time, position angle, heliographic latitude, height, etc. Letters in the last column are used to classify the prominences according to their brightness, the chromosphere being used as the basis for this comparison. Thus, *v* denotes a prominence which is as bright as the chromosphere and *vv* signifies a prominence of the brightest class observed. When the letter *d* is used the prominences are considered to be well defined, though less bright than the first two, and when *dd* appears the light is so feeble that it is comparable with that of the spectrum. The second part shows the distribution of the prominences in zones of 5° area, under each quadrant separately, and the third part gives the mean areas in each zone for every month of the year. Part four shows the number of prominences and their areas for the various zones in each quadrant, and the last part supplies a useful summary of the work for each month. The last eight pages are devoted to the observations of sunspots in 1937 at the University of Valencia. Most of the observations were carried out by M. Martin Lorón and were checked by R. Carrasco. Reductions of observations and computations were effected by E. Gullón.

CANCER RESEARCH

THE annual report for 1943 of the director of the Imperial Cancer Research Fund* makes encouraging reading, not because any startling or dramatic results emerge, but because the problem continues to be assailed on sound scientific lines by a number of different methods which are fully coordinated. Dr. W. E. Gye reports that during the past year work has centred almost entirely on experiments relating to mammary cancer in mice, the induction of cancer with pure chemicals, the action of hormones on the pituitary body and on the prostate gland, and to chemotherapy.

As regards carcinogenesis, H. G. Crabtree's earlier work has shown that a series of halogen compounds, graded with respect to their power of checking cell-glycolysis, could retard the development of skin tumours induced by pure chemical substances. The halogen compounds used could also affect other chemical cell-mechanisms, in particular those involving the sulphydryl group; for example, glutathione, enzymes containing sulphydryl groups as active centres, or the normal synthesis of proteins with sulphur-containing amino-acids in their essential composition. Recent observations suggest that sulphur metabolism is a factor in the artificial induction of cancer; it may also assist in determining the occurrence of spontaneous mammary tumours in inbred strains of mice.

The general growth-inhibiting properties of many carcinogenic and non-carcinogenic hydrocarbons seem to be related to the depletion of sulphur-containing amino-acids which co-operate in their elimination. Experiments have been made on the effect of tumour induction when sulphur metabolism is disturbed. One method consisted in the application of bromobenzene to the skin. This substance in the organism is detoxicated by combining with cysteine and is then eliminated as a mercapturate. Crabtree has demonstrated the inhibiting effect of bromo-benzene on the formation of skin tumours in mice by 3 : 4-benzpyrene. The earlier types used in these inhibiting experiments, by virtue of their mobile halogen atoms, can react with the sulphydryl type with elimination of halogen acid, while the present type reacts by a coupled oxidation in which the relatively unreactive halogen remains as a constituent of the resulting mercapturate. This inhibition of tumour induction probably occurs with both types of compounds under conditions of localized sulphur deficiency, which suggests that sulphur metabolism is intimately concerned in the processes of chemical carcinogenesis.

Dr. B. D. Pullinger has continued her study of the Deelman phenomena, that is, the localization of tumours in scars and healing wounds. Her experiments indicate that trauma, as represented by excised wounds, has a slight stimulating action in increasing tumour incidence. Her work also suggests that the intervention of some specific carcinogenic chemical is necessary to stimulate or originate tumour growth, as well as the added non-specific action of trauma.

Cramer and Horning's work has shown that there is a reciprocal action between the sex organs and the pituitary body. Pursuing this work, Dr. Vaquez-Lopez has studied the effect of œstrinization in a number of species of animals. In the hamster, for example, when œstrogenic substances (œstradi benzoate and diethylstilbœstrol) were subcutaneous implanted, the epithelial cells of the pars intermed of the pituitary body multiply and invade t posterior lobe, which consequently enlarges. T invasion often replaces the whole of the pars nervo and may extend along the neurohypophysis to t brain. In mice a similar enlargement takes place the anterior lobe of the pituitary body. This ho monal stimulus causes an extension of a norm process; it is an invasive phenomenon, not a ne growth, for there is no defensive reaction of ner tissue to the emigration of intermedia cells, such occurs in the event of an invasion by alien cell Long-continued treatment with œstrogens gives ri to profound changes not only in the organs of intern secretion, such as pituitary gland, the supraren glands and the islets of Langerhans in the pancrea but also in the testis, the mammary gland and th prostate. This work, then, bears upon the enlargemen of the prostate in old age and, possibly, its tendenc to malignant disease. Horning is now investigatin the effects of œstrinization on the prostatic glands pure-line mice of high and low incidence of mammar cancer.

Interesting work has been done by Dr. R. J Ludlow and Miss H. Barlow on tissue cultures. Th cell characteristics of primary tumours, both spontaneous ones and those induced by œstrin and chemicals, have been studied, as well as the action o malignant and non-malignant cells on fibroblasts *i vitro*. The latter research leads to the conclusio that some product of the metabolism of growin epithelial cells stimulates the growth of fibroblasts

Mammary cancer in inbred strains of mice, o which Bittner, Andervont, Little and W. S. Murra in America have recently done much work*, has bee further studied by Dr. Ludford and Dr. L. Dmochowski, and Dr. Ludford and Miss Barlow have continued their work on chemotherapy.

Knowledge of cancer increases year by year, an this report is no mean contribution to a proble which is gradually emerging from obscurity.

PROTECTIVE SYSTEMS FOR RURAL ELECTRICAL DISTRIBUTION

A SYMPOSIUM of four papers on this subject was presented before the Institution of Electrical Engineers in London on May 12. In the first paper, by D. C. Field on systems up to 33 kV., the general principles of protection are discussed, emphasis being laid on the importance of considering the prevention of faults as well as their isolation. From an analysis of the causes of interruptions, which shows that a large number are only transient, and from the special conditions pertaining to a rural system, it is concluded that it is preferable to restrict the number of points at which automatic protection is provided, in order to facilitate the rapid resumption of supply. The methods of protection adopted in one large rural area are briefly described, together with a summary of the experience gained in operating several classes of equipment, including arc-suppression coils, auto-reclose switches and fusegear.

The second paper, by O. Howarth, is confined to 11 kV. networks and consists of a description of the ea supplied by the Lancashire Electric Power Co., nd of the nature of supplies afforded in that area. he 11 kV. distribution system and the protective rangements employed thereon are described, and gures showing availability of supply to consumers uring a period of one year are given. The testing cessary to ensure satisfactory functioning of the otective gear is also dealt with. The experience of he Lancashire Electric Power Co. indicates that with duplicate tail-end feeder system, simple overload and arth-leakage protection will ensure the minimum of nterruption of consumers' supplies provided adequate sts are made to prove the reliability of the gear. Where two or more feeders operate in parallel between nding and receiving stations, and provided the load apped off along the route does not exceed about 0 per cent of the normal load of the feeder, very atisfactory discrimination can be obtained with arallel-feeder protective systems.

In the third paper, by R. W. Steel and A. W. llwood, systems up to 33 kV. are considered, and he importance of installing suitable and efficient rotective apparatus on rural networks, at all stages f their development, is emphasized. A typical proective scheme, including arc-suppression coils, for an 1 kV. and 33 kV. rural distribution system which has een put into operation in a particular area of supply s described, and the reasons leading to its adoption re given. The practical difficulties met with in ecuring efficient operation and of carrying out roper maintenance are discussed and some statistical ecords of fault interruptions are presented. These ndicate the number and type of faults causing total r partial failures of supply and show the conditions under which the protective gear is called upon to unction. The nature of the faults which occur on ural networks is analysed and a suggested standard orm of keeping fault statistics is put forward for general adoption by undertakings distributing in ural areas.

The fourth paper, by K. I. Brown, deals more particularly with the automatic selective isolation of sustained earth-faults on a network protected by Petersen coils, and explains what is believed to be a unique method evolved for the protection of a grid network of 37·5 kV. transmission lines against line-o-earth faults, which enables automatic selection and isolation of a section subjected to a sustained fault to take place without utilizing earth fault current for the operation of protective relays, or pilot wires between sectionalizing stations remote from one another. The scheme provides for the installation of Petersen coils together with special automatic selectors and associated equipment, and has been employed with considerable success since 1936 for protection of the Ganges Canal hydro-electric grid in the United Provinces, India.

The paper shows that by introducing Petersen coils and automatic selector equipment to the system, almost complete immunity from outages due to temporary line-to-earth faults had been achieved, and that in the case of a sustained line-to-earth fault the affected section can be selected and isolated automatically within a period of 30 sec. from the instant of fault, without any 'kick' being experienced by the power stations. No pilot wires are required between selector stations. The existing overload relays continue to protect the system against line-to-line faults, and if desired the original form of earth-leakage protection may be restored to the system by the manipulation of earthing switches.

To certain criticisms of the scheme that (*a*) there is the possibility of line surges occurring due to switching on a system entirely protected by Petersen coils, and (*b*) the interruption in supply to substations connected to healthy lines between switching points must of necessity sometimes be experienced, it can be replied that no surge effects have been observed and the transformers, switchgear and line insulators have not been affected thereby, while since the majority of faults recorded clear before any sectionalizing takes place and as sustained earth faults are infrequent, momentary interruptions to load points are few. The probability of the selectors having to complete full sequence of operation in the event of a sustained earth fault is small, as there are eleven sections on which the fault may have occurred and it is only in the event of the fault being on the last section in the series, or in a substation structure, that the full sequence of operation takes place.

THE TERMITES OF AUSTRALIA

By Dr. A. D. IMMS, F.R.S.

UNDER the above title there has recently appeared a timely and much needed monograph*. The author, Mr. G. F. Hill, has been an active worker on termites for many years and has an unrivalled acquaintance with these insects in so far as Australia is concerned. There are many difficulties to be contended with in the study and investigation of termites, and it is for this reason that monographs are badly needed from nearly all parts of the world that are inhabited by these creatures. Excluding the United States, which has a relatively meagre termite fauna, Australia is to be commended in giving a leading hand by furthering publication of an account of her native species. But the availability of a competent authority is about two thirds the battle—other lands are not so far equally favoured. India, perhaps more than any other part of the British Commonwealth of Nations, needs a proper monograph on her rich and vast termite fauna, that is productive of almost incredible damage to human effort. A sound monograph on this order is worth many of those on the more obscure orders, and it is to be hoped that a competent worker will be forthcoming one day, not too far distant, who will cope with the task.

But, as previously said, the difficulties are manifold when it comes to identifying these insects. The soldier caste affords the best and most reliable character—the winged imagines are seasonal and not so often met with in consequence, while the workers (that have earned for termites their notoriety as destroyers of products serving man's convenience) show ill-defined features that make their specific determination a thing of great uncertainty. Apart from the incidence, then, of three different castes of individuals in each species, it needs to be taken into account that two or more different species may inhabit the same mound or piece of wood. It often happens that two or more species of very distinct habits are almost indistinguishable in form and structure, and that individuals of the same species may differ very much in different regions so as to be mistaken as belonging to more than a single species. Difficulties of this kind have naturally given rise to much confusion regarding the specific identity of so many of the Australian termites, as elsewhere.

---

* Termites (Isoptera) from the Australian Region. By Gerald F. Hill. Commonwealth of Australia Council for Scientific and Industrial Research. 479 pp., 353 text figs. and 24 plates. (Melbourne, 1942.)

Much spade work has been undertaken by Mr. Hill in getting discrepancies of this type properly cleared up. During the progress of this work about nine thousand termite colonies have been examined. Altogether 217 species have been recorded from the region under review, which includes also New Guinea and islands south of the equator between 140° E. longitude and 170° W. longitude.

Among this rich fauna is included the most primitive of all termites—*Mastotermes darwiniensis*, which happens, also, to be the most destructive among the Australian species. A thorough study of this 'key' form should throw much light on the many outstanding problems of termite economy and would form an admirable subject for a young and promising Australian zoologist to embark upon. The present monograph loses nothing by the letterpress being reproduced photolithographically owing to need for economy, and the line drawings form a valuable adjunct. In a short notice of this kind little more can be written other than to direct attention to the importance and excellence of the work in question, which will probably long remain a standard monograph.

FORTHCOMING EVENTS

Saturday, July 3

NUTRITION SOCIETY (JOINT MEETING WITH THE FOOD GROUP OF THE SOCIETY OF CHEMICAL INDUSTRY) (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Discussion on "Milk" (Chairman: Prof. H. D. Kay).

LONDON MATHEMATICAL SOCIETY (JOINT MEETING WITH THE LONDON BRANCH OF THE INSTITUTE OF PHYSICS) (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2 p.m.—Dr. A. C. Aitken, F.R.S.: "Matrices in Practical Mathematics"; Dr. L. J. Comrie: "Computational Methods and Mathematical Tables"; Mr. H. L. Blackburne: "Mathematical Solutions by Models"; Dr. S. Whitehead: "Applications of Elementary Mathematical Processes, with special reference to Circuit Theory".

Saturday, July 3—Sunday, July 4

TOWN AND COUNTRY PLANNING ASSOCIATION (at the Waldorf Hotel, Aldwych, London, W.C.2), at 10.30 a.m.—Conference on "Town Planning, Housing and Full Employment".

Tuesday, July 6

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 5 p.m.—Annual Meeting.

Friday, July 9

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. R. O. Redman: "Spectrographic Observations of the Total Eclipse of 1940 October 1; 3: The Spectrum of the Extreme Limb of the Sun"; Dr. R. v. d. R. Woolley: "Note on Convection in the Sun"; Mr. A. W. J. Cousins: "Photo-visual Magnitudes of Southern Stars".

INSTITUTE OF PHYSICS (JOINT MEETING WITH THE INSTITUTION OF ELECTRONICS) (in the Reynolds Hall, College of Technology, Sackville Street, Manchester), at 7 p.m.—Dr. A. Sommer: "Photo-electric Cells".

Saturday, July 10

INSTITUTE OF PHYSICS (INDUSTRIAL RADIOLOGY GROUP) (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Open Discussion on Industrial Radiology.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT MISTRESS WITH HOUSEHOLD AND SOCIAL SCIENCE QUALIFICATIONS, INCLUDING BIOLOGY AND HYGIENE—The Clerk to the Governors, Mid-Essex Technical College, Chelmsford (July 7).

LECTURER IN BUILDING CONSTRUCTION, GEOMETRY AND SCIENCE, AND ELEMENTARY MECHANICS in the Junior Building School of the Newport Technical College—The Director of Education, Education Offices, Charles Street, Newport, Mon. (July 7).

ASSISTANT MASTERS FOR (*a*) MATHEMATICS, (*b*) SCIENCE, INCLUDI BIOLOGY, (*c*) ADVANCED MECHANICAL ENGINEERING SUBJECTS, ENGINEERING SUBJECTS INCLUDING ELECTRICAL ENGINEERING A WORKSHOP TECHNOLOGY—The Principal, Enfield Technical Colle Queensway, Enfield, Middlesex (July 9).

ASSISTANT MASTER IN THE JUNIOR TECHNICAL SCHOOL, WE QUALIFIED TO TEACH MATHEMATICS AND SCIENCE—The Princip Royal Technical College, Peel Park, Salford 5 (July 9).

TEACHER (TEMPORARY) OF SCIENCE AND MATHEMATICS, and TEACHER (TEMPORARY) OF WORKSHOP PRACTICAL (ENGINEERING) A TECHNICAL DRAWING—The Principal, Stockport College for Furt Education, Stockport (July 10).

JUNIOR LECTURER AND DEMONSTRATOR IN THE DEPARTMENT MECHANICAL ENGINEERING—The Registrar, The University, Liverpo (July 14).

DEMONSTRATOR (MAN OR WOMAN) IN THE PHYSIOLOGY DEPARTME —The Warden and Secretary, London (Royal Free Hospital) Sch of Medicine for Women, 8 Hunter Street, London, W.C.1 (July 16).

COMBINED POST OF FULL-TIME (ACTING) RADIOTHERAPIST TO T LIVERPOOL CANCER CONTROL ORGANIZATION and (ACTING) MEDIC DIRECTOR OF THE RADIOTHERAPEUTIC DEPARTMENT OF THE LIVERPO RADIUM INSTITUTE—The Hon. Secretary, Liverpool Cancer Cont Organization, 66 Rodney Street, Liverpool 1 (July 24).

HEADS OF THE DEPARTMENTS OF PHYSIOLOGY, MEDICINE, A SURGERY—The Bursar, Royal Veterinary College and Hospital, The University, Reading (October 1).

PSYCHIATRIC SOCIAL WORKER—The Medical Superintenden Springfield Mental Hospital, Tooting, London, S.W.17.

TEACHERS (MEN OR WOMEN) FOR THE FOLLOWING SUBJECTS FOR T DAY SCHOOL: JUNIOR MATHEMATICS; MATHEMATICS; GEOGRAPHY GENERAL SCIENCE—The Clerk to the Governors, South-West Ess Technical College and School of Art, Forest Road, Walthamsto London, E.17.

TEACHER OF ENGINEERING SUBJECTS—The Principal, Technic Institute and Day Technical School for Boys, Gravesend.

SCIENCE MASTER TO TEACH MAINLY BIOLOGY in connexion with Pre-Agricultural Course for Boys in the Maidstone Technical Institu —The District Secretary, Mr. A. W. Peacock, 13 Tonbridge Roa Maidstone.

CENTRAL PRODUCTION ENGINEER—The Ministry of Labour an National Service, Central (Technical and Scientific) Register (Referen No. C.1609X), Alexandra House, Kingsway, London, W.C.2.

ENGINEER (temporary staff) for the Nigerian Government Publ Works Department—The Ministry of Labour and National Servic Central (Technical and Scientific) Register (Reference E.684, Alexandra House, Kingsway, London, W.C.2.

CO-OPERATION IN SCIENTIFIC RESEARCH IN THE BRITISH EMPIRE

A FEATURE of the discussions at the conference on the Planning of Science arranged by the Association of Scientific Workers last January was the constant reference to the need for closer inter-Allied co-operation, and in particular to the need for extending the arrangements by which young workers from the war laboratories may visit their colleagues in other countries, not merely for discussion but also to work side by side in allied teams. The value of fostering contacts between workers in the universities, in industry, and in Government departments, and of frequent exchange of staff as well as of information, was clearly recognized, and was afterwards reiterated by Dr. P. Dunsheath in a paper before the Royal Society of Arts. Similarly, the importance of establishing a central information bureau from which such scientific and technical liaison could be conducted as to ensure that departmental missions are at least in touch with one another, and that those at the centre know what all, and not just a few, of the various departments are doing, no longer appears to be in dispute.

Specific recommendations have now been made in a report of the British Commonwealth Science Committee set up under the chairmanship of the president of the Royal Society in October 1941 as the outcome of a conference held at the Royal Society's rooms on October 7, 1941. This conference included representatives of the Dominions and India, and of the Royal Society ; and the secretaries of the Medical and Agricultural Research Councils and the secretary of the Department of Scientific and Industrial Research, Lord Hankey and others were invited. The general objectives were to secure scientific co-operation in tackling the emergency problems of the immediate post-war period and to ensure that the most should be made of our common scientific resources after the War for improving both scientific knowledge itself and the life of the peoples of the Empire ; in particular, the conference was to consider means of promoting co-operation between the several parts of the Empire in scientific research and in the application of science to technical, biological, medical and economic problems.

The report now issued summarizes the discussions at the twelve meetings of the Committee. These discussions have been focused mainly on schemes for collecting and disseminating information, for example, on the model of the Imperial Agricultural Bureaux ; schemes for collaboration in research within the Empire ; and schemes for facilitating visits and readier movement of research workers, university teachers and others within the Empire. The extension of such schemes to collaboration with the United States has also been discussed. The Committee has aimed at discovering, so far as possible, what is lacking in the existing machinery, and it stresses that the implications of the Atlantic Charter point inevitably to the need for closer political, social and technical collaboration with the United States, the U.S.S.R., China and other countries or regions. Planning collaboration in well-defined spheres of activity is a pressing need, first through the establishment of the best agreed co-operative machinery for exchange and dissemination of technical information and later by planning for co-operative research on problems common to all or to certain regions.

As an example of such a regional scheme, the report cites Brigadier B. F. J. Schonland's suggestion that institutes for research on African problems might be formed in such subjects as tropical diseases, social anthropology, native languages, ethnology, geology, geophysics and meteorology. Many important problems of world-wide significance are being investigated independently in Empire countries and elsewhere, and the advantage which would result from co-operation between those countries willing to pool resources for the common good need scarcely be stressed. The Colonial Research Committee recently established under Lord Hailey's chairmanship should facilitate such co-operation, and the researches which may be undertaken by the Committee should also be co-ordinated with work in the Dominions and elsewhere.

It is unnecessary to reiterate here the examples cited in the report of fields in which such co-operation is called for and is related to programmes of post-war reconstruction, or to enumerate the various international organs already in existence, such as the International Locust Research Committee, the World Power Conference, and the International Institute of Agriculture. Proposals for the re-organization of some of these, for example, the International Health Organisation, were already under consideration at the outbreak of the War, and most of these services will need reviewing and probably revising in the most suitable form and on as wide an international basis as possible after the War. For the re-establishment of such co-operation Anglo-American initiative may indeed be essential, and further consideration will have to be given to machinery for close collaboration in research and the establishment of laboratories and institutes common to the Empire and the world.

On this question the report therefore makes three specific recommendations. First, that a suggestion be made to the Governments of the various English-speaking countries that they should consider the possibility of maintaining permanent scientific and technical representation in London and possibly also in other capital cities of the English-speaking world. Secondly, that such scientific and technical representatives of the Dominions and India permanently established in London should, together with official representatives of science in the United Kingdom and the Colonies, be constituted a British Commonwealth Scientific Collaboration Committee, to act with the Royal Society in the discussion of topics of common interest, to keep in touch with all agencies and organizations for the collection and dissemination of scientific information, to further schemes for co-operation in research, and to make such recommendations and proposals for common action as may seem fit. Thirdly, that if scientific and technical representatives of the United States and of othe countries outside the British Commonwealth ar established in London, arrangements should be mad to seek their co-operation, so far as may be practicabl and appropriate.

The wisdom of this last recommendation is so paten that the support of all scientific workers is assured The report itself indicates that the New Zealan Council for Scientific and Industrial Research, th National Research Council of Canada and the Nationa Research Board of South Africa are already prepare to support such collaboration. Scientific workers, however, should demonstrate emphatically their support both through their professional associations, and also in their private capacity as individual citizens, so that the Government can be in no doubt as to the extent of the support which is forthcoming for the proposal. There should be no ground for any pretence that the recommendations are in advance of what scientific workers as a body are prepared to endorse and wholeheartedly to implement.

The first of the six recommendations of the report, however, is one which makes even stronger demands for immediate support and response from scientific workers. There are, as the report points out, a number of bodies collecting and disseminating scientific information which might be assisted if made part of a wider scheme, and in particular, collaboration in the production of scientific abstracts of high quality for the common use of the English-speaking world would have the strong support of the Committee. In accordance with this, the Committee recommends that the Royal Society should invite representatives of the appropriate scientific, technical and official bodies to meet as early as possible this year to discuss in general the further development of abstracting and information services as a co-operative effort between English-speaking countries, and, if agreed, to propose machinery for making a more detailed inquiry and for formulating more definite plans.

The report touches here on a demonstrable weakness in the organization of science. Besides the overlap between *British Chemical and Physiological Abstracts* and *Chemical Abstracts* and *Science Abstracts*, there are numerous examples of overlap and duplication in more limited fields, such as analytical chemistry and particular industries, which are hard to defend to-day against the charge of extravagant use of labour and material. That this is now being more widely appreciated is indicated in an inquiry, sent out almost simultaneously with the publication of this report, to members of the Society of Dyers and Colourists, asking for an indication as to whether or not members would be prepared to dispense with the abstracts which are at present included in the *Journal* of that Society. Further opportunities for rationalization in a comprehensive scheme are clearly to be found in the abstracting services and publications of research associations and similar institutions, although here are to be found one or two examples of the effective elimination of duplicate effort. In the medical and biological sciences the position is much worse, and there are really wide opportunities of eliminating duplication of effort even within the limits of Great Britain.

There can be little doubt that rationalization in this field will be best secured under some comprehensive scheme covering all the sciences. Such a scheme will have the best chance of dealing with the difficulties in regard to nomenclature, bibliographic detail and the like which are apt to be a source of friction in smaller schemes when co-operation between allied sciences is involved. Moreover, under a large scheme, the savings to be achieved by genuine rationalization should make it unnecessary to continue some of the abbreviation practices to which some abstracting organizations have been forced in recent years owing to lack of resources. Such practices have been a minor source of irritation to many of the present users of such abstracts, and they offer a real obstacle to the wider use of the abstracts in their present form. Again, a central scheme is far better placed to encourage the use of new means for the rapid dissemination of information, such as microfilm, and to explore the possibilities of such developments.

The report shows that the Royal Society's committee is fully alive to the possibilities and to the need for rationalization of effort in the provision of an efficient and widespread information service. By extending, for example, to cover a wider field, the principle of the Imperial Agricultural Bureaux, which are maintained by a central organization, though working in separate institutes, greater financial stability, prevention of duplication and a closer co-ordination of the whole information service should be achieved. Rationalization of existing British organizations throughout the Empire should only be regarded as the first step. Scientific research and technical development have a fundamental bearing on economic factors, and the organization in each country for the collection and correlation of scientific information should be such that it would aid the collection of data by the economic bureaux.

The Committee is clearly right in holding that this whole issue must be the subject of detailed inquiry before any definite proposals are put forward. None the less, while such inquiry is proceeding, scientific workers could do much to prepare the way and to overcome the prejudices and other obstacles which have rendered abortive earlier and more limited efforts in this field. The growing complexity of science and technology, and the penetration of science into almost all human activities, make it essential that every effort should be made to provide as efficient an information service as possible ; this is no longer a matter which concerns scientific workers alone.

If rapid progress can scarcely be looked for in the matter of this first recommendation, the situation is entirely different in regard to the last two recommendations of the report. There appears to be no good reason why immediate steps should not be taken to direct the attention of the Governments concerned and of independent agencies to the very great value of frequent and easy personal contacts and exchanges between research workers and students in various countries, which air transport should greatly facilitate in the future. For this purpose, largely increased funds would be required, and some plan for co-ordination would require working out with the various grant-giving bodies.

Similarly, there should be no delay in pointing out to the various Governments, universities and other authorities the advantages which would result from the institution of a system of sabbatical leave, to enable the scientific and technical staffs of academic, Government and industrial research organizations to make fuller use of such facilities as may, from time to time, be available for visits to other parts of the English-speaking world. In the whole of its remarks on this question of the flow of personnel, the report shows that the Committee is fully abreast of the most progressive thought in science and in industry. Here, as elsewhere, the report gives a clear lead to all scientific workers who wish to see science making a fuller contribution both to the war effort and to the task of post-war reconstruction. On them now rests the responsibility of seeing that that lead is followed, and that their existing organizations and societies do all that is possible to secure and support the necessary action required to implement the recommendations.

IMPACT OF SOCIAL INFLUENCES UPON ART

The Psychology of Cultural Change in Painting
By Dr. R. W. Pickford. (British Journal of Psychology, Monograph Supplements, 26.) Pp. vi+62. (Cambridge : At the University Press, 1943.) 8*s*. 6*d*. net.

NO painter can avoid some degree of self-expression ; he may introduce a large amount of it, but in any event he is unlikely to be utterly objective. Whatever his choice of subject and treatment, his composition will be psychologically significant. What is perhaps even more important is that he has expended energy in the making of his picture and, through strife and toil, has arrived at something which, by highly complex paths, represents at last a function of his social environment. Thus, in the introduction to his monograph, Dr. R. W. Pickford paves the way for the detailed development of his theme. He is concerned neither with techniques nor with æsthetics ; his task is to discuss social influences in their impact upon artists. In so doing, he performs a double service—to the man of science who realizes the profundity of all that is involved in creativeness (in whatever form), and to the historian, who is sometimes curiously reluctant to see in paintings the documents he most may need.

Naturally, this is scarcely a contribution for the layman. It is a closely woven pattern, cautious in the intertwining of warp and woof. However, one criticism the non-initiated might be tempted to make, and it may be worth while to anticipate it now. He would assert, in effect, that all this close analysis only amounts to what anybody with but a modicum of common sense would surmise in less time than that taken to say Jack Robinson. Examples are the effects upon leaders of those whom they lead, of frustration and of thwarted purpose, and so on. But in this he would be mistaken. A superficial interpretation of the nature of genius is usually rash, and there is a world of difference between riding roughshod over the minutiæ of circumstance inherent in some artistic or intellectual upheaval, and the enviable clarity of exposition, step by step, which is a feature of Dr. Pickford's approach.

A reasonable distinction can assuredly be drawn between a study of groups and individuals on one hand, and the psychology of cultural change on the other. This dichotomy serves well in the present instance, dividing the whole monograph into two approximately equal parts. Furthermore, it is easier for the reader to be introduced to the personalities crossing the stage before being asked to pass judgment upon the setting or settings which in fact contained them. The result is a very human assessment of the whole problem, or, as the author would call it, "comradely". The reviewer wishes, however, that examples from the West somewhat earlier than the French masters could have been discussed; for example, the Italian primitives and the Flemish painters. Certainly group tendencies as well as directional inhibitions were strong in both these movements. The point seems to emerge that it is just as advantageous (to put it mildly) in psychological research to take the simplest case as material upon which to work as it is in the more exact sciences. Of course, it is far from universally true that simpleness—not necessarily simplicity—of technique connotes the simple mind, but it was probably so in, say, Siena in the fourteenth century, thus providing a good springboard from which to attack later complexities.

The analysis of Chardin, Goya, Daumier and Cézanne is most illuminating. Dr. Pickford is thus led to discuss ambivalence, the characteristic possessed by some people of displaying acceptance and rejection of the same situation either alternately or simultaneously. Apparently this did not afflict the first two of these artists, but was strong in Daumier and terrific in Cézanne. When present, it is clear that severe mental conflicts will arise. It is significant how similar in some ways these dispositions are to the transitional properties frequently observed in physics and chemistry. The parallel must not, however, be pressed too far, for whereas we have recently learnt (for example, in crystallography) how to insert missing members into a series, if Nature is not kind enough to provide them, we cannot yet do this for human material. Until we can, our results will often be patchy, though with the vast amount of 'stuff' available, it is presumably worth combing very thoroughly in attempts to fill the gaps.

The Barbizon painters represent a small nexus of men, compact and bourgeois, very susceptible to natural scenery and to the appeal of tranquillity. Whence comes this latter characteristic ? It is hard to say, but perhaps permissible to mention that such a totally different person as John Keble was writing of the 'soothing' element at very closely the same moment in the first edition of his "Christian Year". Corot appears as the undisputed leader of the group. He possessed qualities amounting to greatness, both as a painter and as a man. Millet, who always enjoyed considerable popularity in Great Britain, was obviously influenced by the Italian primitives. Both for the Barbizons, and for the Pre-Raphaelites (to be discussed later), it seems that a forceful literary critic was needed to make the work of psychological groups fully effective. This was achieved for the former by Thoré, and for the latter by Ruskin. At this distance of time, it is easy to underrate how much these two writers did for their causes. Another condition for effectiveness is the presence—in some form or another—of interpreters, who, as Dr. Pickford remarks, resemble stepping-stones to conduct the public to the great masters themselves. This was done admirably by the lesser lights of the Barbizon school.

Perhaps it is as well to recollect what a very specialized study this cultural change in painting is. Unlike other means of approach, it is competent to offer suggestions for an evaluation of kindred problems by comparative methods. To-day, for example, we are being pressed for an enhanced publicity campaign in the interests of science. It is hard to avoid the conclusion that history is but repeating itself. Once again the question is: "How can they hear without a preacher ?" Stepping-stones of one kind or another will apparently always be needed if the creativeness of supreme minds is not to become sterile, and their contributions unheeded. What the Barbizon group in particular has to teach is that this widening of influence is possible without disturbance of genius at the top. But the balance is a delicate one. Corot was a great enough personality to appreciate the necessity for diffusion, but to maintain inviolate the fountain-head.

We are thus invited to examine the Barbizon's group structure. A most intriguing short paragraph on p. 14 almost implies—though it does not exactly say so—that its character was that of a *Gestalt*. Admirers of Wertheimer will be quick to notice a parallel between Dr. Pickford's pattern of these men and his "celestial orchestra" in which, as Koffka remarks, little would be gained by restricting attention to the part played by each angel. Important, indeed essential, as every performer is, the meaning of the work resides in its 'wholeness', that is, in its *Gestalt* character. That this is, broadly, the direction of thought seems probable from a remark (p. 46) on stable configurations, and their part in conservation. Clearly, there is something akin to Le Chatelier's principle in physical chemistry in operation here.

Rousseau's personality—as a "Barbizon", and as an individual—is of great interest. He was given to excessive repainting of detail. In acting thus, he expends much labour without reducing the free-energy of his picture appreciably: for a given organization he may even deviate from the minimum, thus increasing the 'potential' and diminishing his approach to satisfaction and repose. So far as the present reviewer is aware, a Rousseau has never been X-rayed. Occasionally, by these means, objective proof is obtained of the way in which artists—not infrequently with disastrous results—have modified and remodified details.

We now approach a major development, the advent of the Pre-Raphaelite Brotherhood. Because its activities ultimately degenerated into being 'just too arty-crafty', it is an error to overlook its originally serious purpose. Dr. Pickford has handled this very tangled skein of dispositions and emotions with distinction. Perhaps it is profitless in the present essay to enlarge upon his careful analysis of the leading personalities involved: they were all more or less abnormal, and some of them exceedingly 'difficult'. What is important is the undoubted influence which the whole affair had upon society, and society upon it. Religion, social reform, æsthetics, intellectualism, and even manners were engulfed in the flood generated by Rossetti and his followers. A pathetic figure, somewhat on the periphery, was Swinburne, interpreted for us largely on Freudian principles. For him, however, and for others like him (if such there ever were), the most lethargic of streams will always find sanctuary at last in the wide ocean spaces. Incidentally, it would have been interesting to know the author's views upon the work and life of Lord Leighton. Too late, and perhaps ill-suited, for full-blooded participation in Pre-Raphaelism, his art is clearly conditioned by it in a very complex and obscure way. His place in the contemporary world of affairs made him and his compositions a 'derived function' of some consequence. It has little to do with stylistic questions, being mainly a matter of social environment.

Chapters 5 and 6 take us far afield, to the contemplation of the Mogul miniatures, and of Russian painting, respectively. The psychological types encountered are so entirely different from those met with in the West that the reader experiences a sharp discontinuity at this point. It would be a pity if he thus inclined to follow his guide less closely here : for the sake, however, of avoiding too wide a sweep, it is proposed now to pass on immediately to the second main portion of Dr. Pickford's theme, namely, the psychology of cultural change itself. In this section the Eastern factors have their full part to play, and with increasing knowledge of them it should be possible to discern their great importance in the transmission of cultures.

Three distinctions are made in this process. First, then, is the passing-on of culture from one large group to another, with fairly permanent contact. Secondly, comes borrowing, that is, the impregnation of a large group by a small one bringing its cultural limits with it. Thirdly, appears grafting, which is a special case of borrowing, when there is an element of force on the part of the transmitting agents.

Contact transmission is, on the whole, the most primitive method, as exemplified by the Bushmen of South Africa. When civilization is more advanced, borrowing and grafting are more likely to occur. A good example of the former is the way in which English landscape influenced the French masters immediately before the Barbizon school. It is well, however, to avoid the conclusion that borrowing alone will suffice to set a cultural change in motion : a more profound impulse such as social constructiveness is probably essential. In this way, borrowing is somewhat catalytic ; experience shows that, as in chemistry, the catalyst may become poisoned, and the reaction comes to a stop.

A question discussed at length is that of omission. It seems that there is continuously at work a kind of mental sieve through which new ideas (of all shades of value) are constrained to pass. In this process, many will be filtered out. This sieve-action is much more complex than a mere mechanical selection, and two persons, starting alike but with unequal 'meshes', will embark upon their respective future enterprises on entirely different lines. The psychology of what is thus rejected—and, therefore, of what is left—is of great interest. There are various possibilities. One is that group tendencies rather than individual ones will predominate. Mogul painting illustrates this, and the same is true to some extent of the history of the Russian ikon. An example of personal omission, on the other hand, is that of Rossetti, who at once had no use for the mystical and poetical ideas about Dante which characterized his father.

The author makes an illuminating comment upon the decay to which, in general, cultures are subject. Decline he believes to be but "the result of very great adversity to construction".

In a review of reasonable length, it has only been feasible to notice a small proportion of the points made by Dr. Pickford. There are many others which will stimulate thought and inquiry from all the diverse interests concerned. What stands out above them all is the insistence upon meaning or significance in painting, as illustrated by cultural change. This transcends mere explanation, and is thus in harmony with modern thought in other directions. It is very much to the good that this movement should gain impetus in one of the most highly developed of the fine arts. The author has produced a scholarly design, seen to advantage against a background at once warm and magnanimous. F. Ian G. Rawlins.

COPERNICUS

Nicholas Copernicus (Mikołaj Kopernik), 1473–1543

Prepared by Dr. Józef Rudnicki. Translated from the Polish by B. W. A. Massey. Pp. viii+53+25 plates. (London : Copernicus Quatercentenary Celebration Committee, 1943.) 10*s*. net.

THE work of Copernicus, whose centenary we have been commemorating, was not limited to astronomy, though to most people he is known only by his astronomical work. The publication under notice surveys briefly his activities. He possessed some artistic skill, and among his manuscript remains is one showing that he dabbled in poetry. This is a religious narrative poem, "Septem sidera", describing the life of Christ up to the time of his converse with the teachers in the Temple. He obtained proficiency in languages also, and published a translation from Greek into Latin of the poems of Theophylactus Simocatta. His work on economics was of considerable importance, and it should be remembered that he formulated Gresham's Law, that bad money, if recognized as legal tender, will drive out good. He also showed the necessity for the ratio of value between gold and silver coins to depend on that between the metals. During the hostilities with the Teutonic Knights in 1521, when he was administrator of the capitulary estates at Olsztyn, he was the only one of the canons who remained at his post, and later the king rewarded him with the title of "Commissary of Warmia" for his work.

All these and other activities besides seem insignificant now in comparison with his revolutionary work in astronomy, which exercised a profound influence in human thought. Perhaps his name would have been almost unknown in history and his *magnum opus* have rested forgotten on the shelves of a monastery library if it had not been for the influence of Rheticus, a young mathematician from Wittenberg. He procured the publication of Chapters 12–14 of "De Revolutionibus", which were included in Copernicus's "Trigonometry", and the issue of the whole work seemed an attractive financial proposition to J. Petreius, the Nuremberg bookseller. As, however, the book appeared very revolutionary in character, a piece of fraud was perpetrated by Andrew Ossiander, the editor, who was a Lutheran preacher interested in astronomy. He replaced Copernicus's original preface, unknown to Copernicus, by an anonymous one of his own, and in this the conclusions of the work were presented as mere hypotheses, without any basis in reality. Unfortunately, a widespread belief that Copernicus had advanced his theory merely as a mathematical device prevailed as a result of this forgery, and Copernicus did not live to correct the error.

The general acceptance of the heliocentric theory was retarded for various reasons. It was claimed that an astronomical system would fit in equally well with observed phenomena if a geocentric view were adopted. Then certain implications of the new theory seemed contrary to the doctrine of the Church, which was prepared to enforce its own views by severe methods, as shown by the fate of Bruno and Galileo. Finally, after the Swedish forces of Gustavus Adolphus had occupied Polish Prussia and Warmia in 1626, Copernicus's books and various documents relating to his life were carried off to Stockholm and Uppsala. There they remained forgotten until the Polish scholar Birkenmajer rediscovered them about the beginning of the present century. In spite of these obstacles the truths first propounded by Copernicus paved the way for those great and far-reaching discoveries which were accomplished by his successors.

THE LIFE-HISTORY OF A PUEBLO INDIAN

Sun Chief

The Autobiography of a Hopi Indian. Edited by Leo W. Simmons. (Published for the Institute of Human Relations.) Pp. xi+460+5 plates. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1942.) 26*s*. 6*d*. net.

THIS book—the story of a Hopi Indian from Arizona—forms an interesting sequel to its predecessor in the same series, which was a similar account of a Kwakiutl Indian from Vancouver Island. In both cases the period covered is one of conflicting cultures—Indian and white—beginning whilst the Indian customs are still holding sway but gradually weakening as the white influence becomes stronger. The cultural setting of the two tribes is quite different, and a good deal of interest is added if both autobiographies are studied.

Don C. Talayesva, the subject of this study, was born in 1890 at Oraibi, a Pueblo village perched on a 6,500-ft. plateau, in constant occupation by the Hopi for at least eight hundred years. In spite of outside influence the Hopi retained their own individuality, both cultural and racial, longer than many other tribes, and therefore provided good material for investigation. Living as they do in a sandy and arid region, water has always been a problem and many of their ceremonies are concerned with making rain and ensuring good harvests, for upon these the Hopi depend for their living. They are a peace-loving, hard-working tribe, but when attacked they defended their mesa-top fiercely and successfully. Conditions of life made transport a never-ending labour, as all food and fuel and most of the water had to be hauled to the mesa top, and all able-bodied members of the tribe took their turn at this task. There is no supreme chief of the Hopi, each Pueblo is independent and the authority, mainly theocratic, is invested in a council of hereditary clan chiefs. Each Pueblo is also organized into exogamous matrilineal clans and every male is a member of a Kiva group, which is a ceremonial organization.

The background, therefore, of Don's life was of an assured and well-defined pattern, and it is all the more interesting to see the results of the impact on him of white culture. For the first ten years he lived with his tribe and the book gives his own detailed and extremely interesting account of a boy's life from his birth. Very notable is the link between him and his maternal grandfather, who took great pains with his education, both material and spiritual. This fine old man roused the boy before sunrise to bathe and exercise and do useful work for, as he used to say, "Work means life".

According to his own account Don was a high spirited and mischievous boy for whom ordinary discipline seemed useless. Accordingly his initiation at nine years of age was made extra severe, and the double whipping he received seemed to have a salutary effect. Next year he went to the reservation school to begin his education, which continued until he was eighteen. By this time, as he says, he had learned to "talk like a gentleman, read, write and cipher", work at various trades and "get along with white men". During his last year at school he had a serious illness which he attributes to Hopi witchcraft and during which, as he still maintains, he died and went to the Hopi spirit world in the west. Here he was cautioned by his guardian spirit and allowed to return to life on condition he behaved well in future.

On his return to Hopiland Don renounced his superficial Christian beliefs and resumed his Indian status, taking part in the rituals and ceremonies and marrying a Hopi girl from a suitable clan. He was still troubled by witchcraft, however, and had various illnesses which he attributed to it, as also the loss of each of his children in babyhood. This last was a bitter blow, as Don was passionately fond of children and felt very deeply the stigma of being childless. When he had almost given up his hope for a child his wife's sister brought her two-year-old son, who was very ill and whom Don nursed back to health and then adopted, treating him very well, if somewhat indulgently. But the upbringing of this boy was far less rigorous than was that of Don himself forty years previously, and one wonders how far the clash of cultures will affect this new generation.

The autobiography is written for the most part in Don's own words, edited by Leo W. Simmons, who stayed in Orabi with Don and became his blood brother. The original document has been much shortened, but is even so almost wearisomely prolonged; the author mentions that Don's sometimes monotonous accounts of his meals had to be cut down, and one wonders if the constant harping on the gratification of his sexual appetite might not have been similarly treated. The description of the ceremonies is intensely interesting, more especially so as Don believed in them so wholeheartedly and constantly refused to relate anything that was considered secret. In fact, this refusal almost led to his breaking off his narrative, and he was only persuaded to continue by being shown accounts of the ceremonies that were already printed.

The book is divided into three main parts: an introduction which outlines the scheme of procedure and then gives a general account of Hopi life in Orabi. The main portion is, naturally, Don's autobiography, the scope of which is outlined above; whilst in the appendix are an example of situational analysis, some Hopi myths and legends, a guide to kinship, and samples of Don's compositions. There are a few illustrations, and a comprehensive index gives a finish to a valuable if rather lengthy volume.

K. Rishbeth.

Plain Words

A Guide to Sex Education. By W. J. Thomas. Pp. 84+10 plates. (Sydney: F. H. Johnston Publishing Co., 1942.) 2s. 6d.

THIS little book is unfortunately mistitled. Unfortunately, because although it scarcely begins to consider the many difficult and thorny problems of sex education, it does give an excellent outline of the physiological facts of sex and some of their sociological implications. Particularly good for such a modest publication are the ten plates, although they are open to criticism on points of detail.

In the first chapter, on "Sex and Wartime Morality", several important questions are begged. It seems to be assumed, for example, that sexual intercourse in marriage implies love and affection, while outside marriage it is "without love" and therefore "an abomination". This attitude neglects the very vital distinction between extra-marital intercourse which is simply promiscuous, and that which is (as is often the case) based on devotion deep and lasting. Similarly the excellent case against the new eroticism of Nazi Germany is weakened by the citing of such 'evidence' as that "Every popular magazine contains at least two or three nude photographs".

Other criticisms of a like nature may be made, and in particular, the author's discursive and repetitive style is rather irritating. But none of this should be taken to condemn the book. It is excellent in its way, and should be as useful in Great Britain as it no doubt will be in Australia.

CYRIL BIBBY.

German for the Scientist (Chemist and Physicist)

By Peter F. Wiener. Pp. xvi+208. (London: G. Bell and Sons, Ltd., 1943.) 6s. net.

THIS book is intended to enable the science student to acquire a reading knowledge of scientific German in a short time. The essentials of grammar and a basic vocabulary are built around a Hans Andersen story. The bulk of the volume consists of passages for translation, and the author has evidently been at some pains to select material which has scientific interest as well as a bearing on the development of his theme. A person with a little previous knowledge of German will find the reading of this book an excellent means of brushing up grammar and rapidly acquiring the ability to make sense of scientific literature. A complete beginner might find himself in some difficulty without a little outside assistance.

The reader is not pampered by vocabularies in the midst of the German text. The passages are from works on chemistry and physics, but this need not dissuade the student of other subjects, for the material is general and the vocabulary widely applicable. Literal translations of the German passages are appended, and there is a full vocabulary.

Papers of a Pioneer

Sir Pendrill Varrier-Jones. Collected by Peter Fraser. Pp. 107. (London, New York and Melbourne: Hutchinson and Co. (Publishers), Ltd., 1943.) 6s. net.

VARRIER-JONES contributed to various medical journals, reviews and periodicals, a number of lectures, addresses and papers treating of many aspects of tuberculosis. The substance of these has been gathered by Mr. Peter Fraser into a connected narrative.

In the first chapter Varrier-Jones points out that the consumptive's life is a damaged one and that breakdowns and relapses will often occur if he is merely given a course of sanatorium treatment. Frequently, too, the patient remains a source of infection to the community. In the three succeeding chapters the author notes how economic considerations prevent the diagnosis of the early case, that for no class of the disabled is a life "sheltered and yet active, protected and yet self-respecting", so necessary as for the tuberculous, and that the problem is not purely medical. Psychology and sociology are mingled with medical considerations. The remaining chapters of the book describe how the author solved the problem by providing medical supervision, treatment and care in the village settlement at Papworth.

The editor has done his task well. The book will appeal to all workers engaged in combating the ravages of tuberculosis. As Lord Horder remarks in his foreword, there could not be a more sincere memorial to Varrier-Jones and his work.

Changes in the Knee Joint at Various Ages

With Particular Reference to the Nature and Development of Degenerative Joint Disease. By Prof. Granville A. Bennett, Dr. Hans Waine and Prof. Walter Bauer. Pp. ix+97+31 plates. (New York: The Commonwealth Fund; London: Oxford University Press, 1942.) 14s. net.

THIS volume summarizes the results of an investigation into the morphological and histological appearances in the so-called normal knee joint at each decade of life. The anatomical changes are described and illustrated in a very fine selection of photographs. Beyond the second decade, all the joints examined showed changes similar to those found in hypertrophic (osteo-) arthritis. The signs of disease were progressively greater with increase in age. Pathogenesis and etiology of degenerative arthritis are fully considered. The authors conclude that the joint changes they describe are essentially due to a degenerative process of hyaline cartilage, and suggest investigation of the factors governing maturation, maintenance and ageing of the hyaline cartilage.

Apart from the scientific value of the accurate observations and the full review of the literature, this book can be recommended to the clinician as a useful reference on prognosis and treatment in arthritis.

Principles and Practice of Chromatography

By Prof. L. Zechmeister and Dr. L. Cholnoky. Translated from the second and enlarged German edition by A. L. Bacharach and F. A. Robinson. Second impression (corrected and with Supplementary Bibliography). Pp. xv+378. (London: Chapman and Hall, Ltd., 1943.) 25s. net.

THE early need for a second impression of this useful translation has raised the difficult problem of keeping the work up to date under wartime conditions. Apart from minor corrections the main text is unaltered, but there is a classified supplementary bibliography containing some three hundred references to work published between 1938 and 1941. This makes the work as complete as can be expected at the present time.

SCIENCE IN SOUTH-WEST CHINA

II. THE BIOLOGICAL AND SOCIAL SCIENCES

By DR. JOSEPH NEEDHAM, F.R.S.
British Council Cultural Scientific Mission in China

IN the previous article (July 3, p. 9) some account was given of the work being done in the physicochemical sciences by our Chinese colleagues under the difficult conditions in this part of Free China.

Exactly how difficult the conditions are is not easy to describe. The students live in badly overcrowded dormitories, and are severely subject to disease such as tuberculosis. Affections such as trachoma, caused by inadequate washing facilities, etc., are common. But the contrast between the life of the normal scientific worker as lived previously and as lived to-day is even more pronounced. Scientific men and women of great attainments are accommodated in rickety old structures around courtyards that cannot be kept clean. The scale of pay has risen only seven times while the cost of living in Yunnan has risen 103 times. I can only compare it with going to live in sheilings on the coast of Argyllshire on less than £70 a year after having held a post at £1,000 a year with a good flat. It is often hard for men whose names are well known in Europe and America to get enough to eat. How many of us would have been willing to live in such exile rather than under the invader's domination in comparative comfort ?

National Southwestern United University

I turn now to some of the biological work proceeding in and around Kunming. First, in the National Southwestern United University there is a good deal of botany going on under Prof. Ch'ang Ching-Yueh. Cytology is represented by Dr. Wu Su-Hsuen (she was trained at Ann Arbor, Michigan), and plant physiology by Dr. Li Chi-Tong, who is making interesting studies on the cleistogamy of the violet plant. There is a nutritional laboratory under the energetic Dr. Shen Tung, where a new and exceedingly rich source of vitamin C has just been discovered—perhaps the richest known—*Emblica officinalis* ("i-gan"), often described as the Chinese olive, but really belonging to the Euphorbiaceæ. In entomology, under Lin Chung-Lo and Lu Chin-Rjêng, much work is going on on the lac insect, an animal of much economic importance to China. Similarly, a complete key to the caterpillars of Yunnan is nearly ready, with special reference to the pests. A complete key to the Yunnan flora, mostly the work of the late Prof. Wu Yuen-Chen, who died last year from hardships encountered here and from inadequate hospital equipment, is now being prepared for the press by Dr. Chien Cho-Po.

Chinghua Institutes of General Physiology and Plant Pathology

Out at Dragon King Pool there are the Chinghua Institutes of General Physiology and Plant Pathology. The former is under the leadership of Dr. T'ang P'ei-Sung, very well known in America, especially at Chicago and Woods Hole, as a collaborator of Dr. R. W. Gerard. Dr. T'ang's flair for originality and ability in younger men has gathered round him, besides Shen Tung, such men as Dr. Yin Hung-Chang, an expert on plant growth hormones from the California Institute of Technology, and Dr. Lou Ch'êng-Hou, a biophysicist who is studying electric responses of plants. It was a remarkable thing t see a complete laboratory for the assay of plan growth substances in these primitive conditions. D T'ang's group is also interested in the mechanims c subterranean fruiting in the peanut, *Arachis hypogeum* a subject again of economic importance for China They have made an extensive series of studies, too on the metabolism and physiology of the silkworm on the streaming of plant protoplasm, and on th production of polyploids. Stimulated by the practica problems confronting Chinese science, Dr. T'ang ha written a book of essays, which it is hoped may b published either in England or America.

The other Chinghua Institute, that of Plan Pathology, is presided over by Dr. Tai Fang-Lan Here all kinds of interesting things also are going on Taxonomy of mushrooms (Chiu Wei-Fan) ; nematode carriers of wheat blight (Yu Ta-Fu) ; genetics o resistance to bean wilt and wheat rust (Fang Chung-Ta) ; morphology of aquatic fungi (Shen Shan-Chong) ; and an extraordinary system of symbiosis or cross-stimulus between certain termites and a certain fungus (Chou Chia-Chih).

The number of papers in manuscript which this Institute and others have accumulated in the past two years is considerable. The fact that scientific papers cannot be adequately printed in China, and the fact that the ordinary mails, owing to censorship and other difficulties, are not such as to encourage scientific men to entrust their manuscripts to them, constitute a menace to the morale of our Chinese colleagues. It is therefore the policy of the British Scientific Mission to facilitate the passage of meritorious papers to Britain and America, for publication in our own scientific journals, until those of China can be got on their feet again.

Drug Research Institute

Not far from the Chinghua institutes, in the same part of the country, is the Drug Research Institute of the Ministry of Education, directed by Dr. Ch'ing Li-Pin. Here special attention is devoted to the botany and pharmaceutics of the indigenous Chinese drugs. This Institute is housed in an old village Buddhist temple, in the main hall of which a gigantic Kuan-Yin image looks down approvingly at the indexed collections of dried plants, the numerous editions of the "Pên Tsao" (the classical Chinese pharmacopœia), and the small printing-press on which a bulletin containing descriptions of new plant species is prepared, and some numbers of which have already been sent to Kew.

Dr. Ch'ing Li-Pin is also the director of the physiological section of the Peiping Academy, together with the zoological section (director, Dr. Chang Hsi), on the shores of the great lake in the Kunming plain. The latter possesses a good working library. Investigations on the plankton of the lake are proceeding (Liu Yung-Pin), on the diseases of the edible fishes of the lake, and on the mollusc Margaria, an edible viviparous gastropod which is very abundant in this region.

National Epidemics Prevention Bureau

In another part of the Kunming area is the National Epidemics Prevention Bureau, under the directorship of one of China's most able bacteriologists, Dr. T'ang Fei-Fên, assisted by Dr. Wang Yo-Wei and a large staff. Here last year five million doses of typhoid inoculation were produced. The Institute also makes smallpox lymph, diphtheria and tetanus toxoid, and a good many other things, including diagnostic antigens such as the Widal test serum for typhus, and the Kahn antigen for syphilis. Preparations are under way for producing typhus vaccine. Dr. T'ang is well known to bacteriologists, immunologists and tropical disease specialists in England and America. His plant maintains high standards of cleanliness in the stables and animal houses in spite of the lack of any running water supply, and an extremely efficient system in the growing, bottling and testing departments. Particularly interesting is the fact that the plant includes a complete glass factory, where neutral glass is made from the proximate ingredients and worked into ampoules and capillaries. The glassworks also produce flasks of all shapes, tubing, condensers, beakers, etc. The story of the plant is an epic in itself. For many months the only available boiler was one which was leaky and unsafe, requiring repairs every evening after use, and with this all the sterilizing apparatus, distilled water supply, etc., had to be run; fortunately no accident took place. Typical of the Institute's pertinacity is the re-utilization of agar by a method specially devised. Dialysis took place from a raft in the lake until the depredations of fishes became too great, and a dialysis tank had to be rigged up on land out of the very few materials available. When commercial supplies of proteolytic enzymes ran out, a hog colony was started, and when the condition of the beasts became such as to yield but poor pepsin, the hogs were fattened by special feeding. This, however, is extremely costly, as indeed is the feeding of all the animals, which has reduced the number of horses, for example, considerably. The Institute is now supplying sera for other United Nations troops as well as Chinese, in the East.

National Provincial University of Yunnan

Within the city of Kunming itself is the National Provincial University of Yunnan, occupying a beautiful site and some of the antique buildings of the old Imperial Examination Halls. It has suffered heavily by bombing, having lost its whole chemistry building. Most of the staff are French-speaking, owing to the former French cultural influence in Yunnan. Thus Prof. Chao Yin-Lai, the organic chemist, is a former collaborator of Prof. Grignard. The courses in the medical school, small but neat, are still all in French. The president, Dr. Hsiung Ch'ing-Lai, is an able mathematician, also French-speaking. Among the heads of departments, however, is Mrs. Tsui Chi-Lan, a morphologist who had her training in Germany. She is now occupied with detailed anatomical studies on the origin of the olfactory organs in Amphibia, preliminary to experimental work on the same subject. She is a pupil of Kraus, Spemann and Hartmann.

The University of Yunnan is at present quite strong in the social sciences, having on its staff Dr. Wang Kan-Yu (a pupil of Prof. Ernest Barker) and especially Dr. Fei Hsiao-Tung, widely known as one of Prof. B. Malinowski's most brilliant students, and for his book on village life in China. Dr. Fei's institute is the Yunnan-Yenching Institute of Sociological and Anthropological Research. It is situated in a small town some hours away from Kunming, occupying rather unusual quarters, namely, a fine old tower or pagoda, dedicated to K'uei-Ko (the god of literature), and placed there because one of the townspeople long ago attained to the dignity of being a Hanlin scholar. The top floor, which contains the image of the god, houses part of the library, and the floor below is the main working-room. The Institute has recently published a number of valuable monographs. Dr. Hsu Lang-Kuang, Dr. Fei's chief colleague, has written on the introduction of modern medicine into a primitive community on the western borders of China, a study which necessitated close observation by him of a cholera epidemic. Like old Nicholas Culpepper in Kipling's story, "A Doctor of Medicine", it seems that the people carry out a number of hygienic measures for quite wrong theoretical reasons, but at the same time have recourse to Taoist and other magic. Other colleagues have written on labour conditions in Yunnan, and on the different types of rural economy in the province.

Chinghua Institute of Statistics and Census Research

In a different part of the same town, there is another of the Chinghua institutes, that of Statistics and Census Research. Headed by Dr. Chen Ta, ably assisted by Dr. Tai Shih-Kuang, this institute carries out experimental censuses of selected regions, observing the reactions of the peasants, checking up on various sources of error, and seeing how best to accustom the Chinese country people to a process which must in due course take place. The Institute is housed in a Confucian temple. An imposing succession of 'pailous' and gates leads into the main court, with its raised platform shaded by a few tall old pine-trees. Within the shrine, in true Confucian puritanism, there is only the golden tablet of the sage, surrounded by those of his disciples, among which those of Mencius and Chu Hsi can be distinguished. Below are the calculating machines and card indexes of the statisticians. It is felt that Confucius would be very pleased to see his house so used in the service of the teeming people of whom he said "First feed them, then educate them".

Confucius, like so many of us to-day, was concerned with problems of government. The proper relation of science to government is a problem which has scarcely yet been solved in Britain or America, still less, therefore, has it been solved in China. At a first glance, it seems that in China there is not yet a sufficiently intimate relation between the university men of science and the growing industries. There is also perhaps a tendency to over-emphasize applied science in the short-term sense at the expense of pure science, especially in the training of students and the sending of them abroad. The scientific man is ordinarily ignored or treated as academic and unpractical; but on occasions is expected to produce practical results without delay by those who have turned a deaf ear to his requests for adequate material support and essential research supplies. The advantage of his advice within the Government organizations themselves is also not fully appreciated.

In these two articles it has been impossible to do more than run over some of the salient features of Chinese science in the far south-west. The main impression which remains with the visitor to the scientific institutions of this vitally important province is of the quite indomitable perseverance and courage which the Chinese scientific workers have shown in carrying on in the remote parts of their country, and of the extraordinary cheerfulness and even gaiety which they show in the midst of their adversity.

STRUCTURE OF α-KERATIN

By DR. IAN MACARTHUR*

Textile Physics Laboratory, University of Leeds

THE structure of the keratins is of interest alike to wool technologists and protein structure analysts. Interpretation, by Astbury and his colleagues[1-4], of the essential features of these fibres in terms of the shape and interlinking of polypeptide chains has earned increasing recognition. The results, achieved from relatively simple X-ray data determined under controlled conditions and used in conjunction with other physico-chemical findings, together with general advances in our knowledge of macromolecular systems, demanded an extension to more intensive X-ray methods. Accordingly, with the support of the International Wool Secretariat, an investigation in progress for some time in the Textile Physics Laboratory, University of Leeds, has aimed at improved range and definition in keratin fibre X-radiograms, with the final objective of a complete analysis of the more crystalline material. Some longer spacings[5-7] were already available, and some preliminary findings have been reported[8]. Analysis is still in its earlier stages, but in view of the interest attaching to very recent work[9,10] with which the present investigation is bound up, a factual publication is not premature.

Technically, use has been made of chromium, iron and copper $K\alpha$ radiation, low-dispersion beams defined by precision ribbon and bore collimators, vacuum cameras, longer-distance photographs, and to some extent monochromatic radiation. The necessarily long exposures have been reduced to reasonable limits by the use of a high-power rotating-anode X-ray generator[11]. Keratin types examined include horn, horsehair, mohair, wool, and especially porcupine quill.

The sharpest and most complete fibre pattern is given by the cortex of African porcupine quill tip (Fig. 1); definition and orientation are poorest for horn. The fibre photograph varies somewhat with the keratin type, at least in completeness, degre of orientation, resolution, and probably also i relative intensities; but the main structure an reflexions are similar. Different specimens of a give type show variations in crystallinity and (slightly) i lattice spacings; while for a given specimen ther are variations also with treatment and condition (humidity, tension, pressure, etc.). The quill photograph will be considered typical for the keratin series

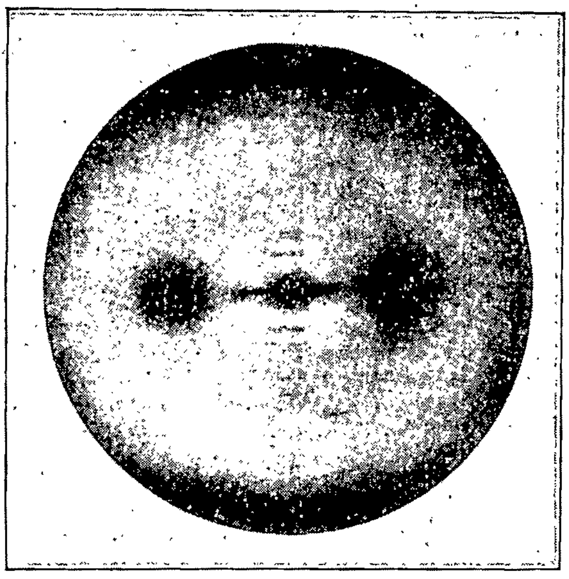

Fig. 1. FIBRE X-RADIOGRAM OF AFRICAN PORCUPINE QUILL TIP. PLANE PLATE; R, 9·8 CM.; COPPER $K\alpha$ RAYS; DRIED, P_2O_5 + VACUUM; COLLIMATOR, 13 CM. × 0·025 CM.

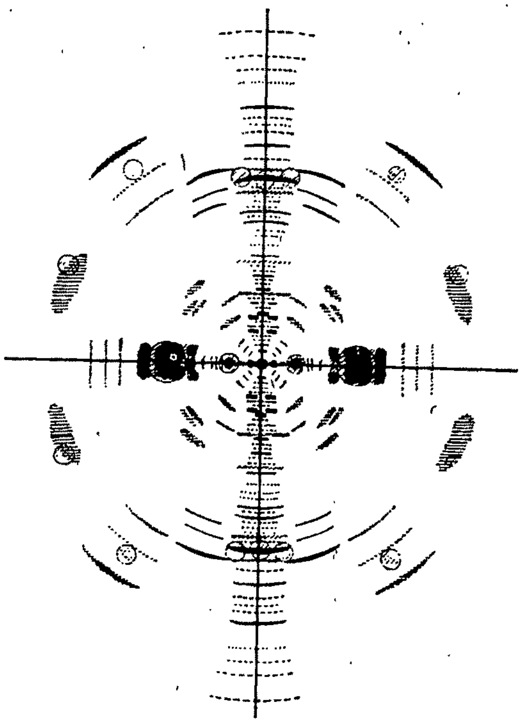

Fig. 2. COMPOSITE CHART OF α-KERATIN DIFFRACTION PATTERN GIVEN BY PORCUPINE QUILL. FIBRE AXIS VERTICAL; PLANE PLATE. (TO D 3A.)

For quill, more than a hundred reflexions hav now been secured in the range 1–150 A.; as show by their interrelation and proportionate response t physical conditions, these refer to the same structure The rich spectrum invites comparison with that o feather keratin[12]. Fig. 2 is a composite diagra showing the α-keratin diffraction pattern for dr porcupine quill tip, down to 3 A. spacings; th circles are the original reflexion areas noted fo animal hairs by Astbury and Street[1].

The reflexions differ in quality. The extensiv meridian and near-meridian series with the dominan line at 5·14 A. are sharp spots or arcs; they characterize regularity along the fibre axis. The equatorial refer to lateral arrangement and include both shar and diffuse reflexions, the latter at least in part du to lack of resolution. Their main groups are strong and sharp long spacings (for example, 81, 41 A. a room humidity) and the strong area at ∼ 9·8 A. This latter is now considerably resolved, showing a fine structure parallel both to meridian and equator, and containing possibly twenty discrete reflexions. The strongest components occur at 9·2 and 10·5 A., the mean, 9·85 A., giving Astbury's side-chain spacing. In the dry specimen non-axial reflexions are poorly defined; but the importance and location of structural water content in keratin are shown in the way the non-axials resolve and sharpen, even ith moderately disperse beams, at definite humidi-es ; meridians are practically unchanged.

---

* International Wool Secretariat Research Fellow.

Stretching beyond a fibre extension of 10 per cent difficult to realize with the highly crystalline quill p ; but in this range the α-structure, in addition to ogressive destruction, undergoes an easily followed versible 2 per cent expansion fibre-axially and an pparent slight reduction in cross-section. Greater fibre tensions yield the β-pattern without superstructural ng spacings. Release of the β-form in water re-enerates the α-pattern, now much weaker in meridian e detail, but sharper and fuller in equatorial solutions ; a similar but less marked change occurs so in traversing the 2 per cent cell-extension range α-keratin. The feature illustrates the difference etween the tighter unions of protein chains giving permanent framework, and the extreme mobility f chains in the rubberoid plastics, in the latter of which retching enormously improves or indeed creates ifficient order to record as a fibre X-radiogram.

Striking inter- and intra-crystalline phenomena ccur with increasing humidity. Meridian spacings re very slightly (less than 0·7 per cent), equatorials onsiderably (3–10 per cent), increased. This recalls omparable temperature phenomena with *n*-aliphatic ng-chain compounds[13,14] and in itself resolves the irection of the axial covalent polypeptide chains om the looser cross-sectional links of ionic, S-S, -bond, or van der Waals type. Differential lateral xpansion with stretching, swelling, or temperature hould facilitate crystallographic indexing. Though e variation with swelling is ample and apparently nisotropic, certain assignments have not yet been ade because of the broad and composite nature of ese reflexions, and the possibilities of other than imple crystallographic cell interpretations.

X-ray interpretation of fibrous protein structure an follow two lines : the broadly physico-chemical r the more rigorously crystallographic. With such ata as those of Fig. 2, the second method becomes creasingly feasible, but special caution attends its se. Not only does lack of resolution occur in fibre -radiograms of macro-units formed of protean chain ystems, but also X-radiation and prolonged stretch-ng permanently affect the keratin substance. There the possibility of two or more phases, not necessarily f identical chemical composition, and that, indeed, o be inferred largely from data for assorted wools. s the 'crystalline' phase a molecular lattice, or is it ue to such parts of a chain system as can form local rder through suitable chemical and spatial charac-eristics ? Are reflexions all normal ones of a unit ell, or may a small number of large units per micelle imension demand sub-indexing, as seems possible or viruses[15] ? Is the diffuseness of certain groups of eflexions due to (*a*) thin or imperfect crystallites, *b*) mere lack of resolution of overlapping spots, c) the diffuse scattering of elastic, thermal, or Raman ibration systems, (*d*) a secondary structure of grids r layers with only average regularity and differing ossibly in reflecting power ? Are we dealing with a nember of a structural series in which intramolecular esidue or chain or grid interchange parallels the tomic or molecular replacements of alloys and solid olutions generally ? Such possibilities, some readily ismissible, will be discussed elsewhere ; it will be rovisionally assumed that the recorded reflexions rise by Bragg scattering.

The sharp meridian (0*k*0) series are orders of a rge unit of pattern along the fibre axis. This unit either 658* or 198 A., the ratio being 10/3. Discrimination is not easy. The latter is a good fit for many full sequences, but lacks a second order, and, in particular, the sharp 5·14 A. spacing seems just too far out to fit. The fine structure of the strong 9·8 A. equatorial is too vague to distinguish between a second order of 198 and a sixth of 658. Fitting to 658 A. is good but less critical. But the number itself is significant. Accepting an approximate 100 per cent chain extension in passing from α- to β-keratin[2], it follows that three amino-acid residues occupy the length of 5·14 A. Thus 658 A. corresponds exactly to 384 (= $2^7 \times 3$) residues. To accord with present chemical analyses (for wool), a molecule would contain $2^6 \times 3^3$ residues, or a multiple thereof. The simple metrical relation of these Bergmann numbers is strongly suggestive. These are easily reconciled crystallographically even if a single chain is chemically representative. In fact, certain simple folds are found to give cell cross-sections that accord with much of the X-ray data, yield a cell containing 2^m3^n numbers of Svedberg units ($M \sim 17{,}500$), and are feasible on general grounds. Not only is this fibre periodicity significant, but the intensity distribution is also peculiar : the dominant meridian spacings and stronger layer line translations expressed as orders of 658 A. are also generally very closely of the form 2^m3^n (cf. Table 1). The order (2^7) of the very strong meridian contains the L.C.M. of the 2^m factors in the proportions of component residues (wool).

The 2^m3^n rule for dominant meridian orders holds best for the longer spacings. For spacings less than 4 A., thus approaching atomic bond distances, the fine structure of the polypeptide chain begins to be appreciable and introduces its own periodicities. Curiously, even the 2^m3^n rule scarcely discriminates for certain between the values 658 and 198 A. For

* The value 642 A. originally quoted[8] was referred to an *unstretched* spacing of 5·06 A. for the dominant meridian[3]; the new value, 5·14 A., should be more accurate.

certain higher orders (2^m3^{3+p}) of 658, this is necessarily so as $198/658 = 2^3/3^3$ to 1 per cent. As shown below, lower orders transfer to orders of 198 A. (to not more than 0·2 off integral) which do not differ from the 2^m3^n rule beyond 1 unit:

Order of 658 A. ..	10	24	33	36	53	63	107	(117)	128
Order of 198 A. ..	3	7	10	11	16	19	32	35	(38·4)

Explanations of periodicities and intensity distributions involving mainly 2's and 3's can be derived from (*a*) crystallographic symmetry operations on a unit of structure, (*b*) a material framework, possibly largely independent of local chemical composition, but involving 2's and 3's (for example, molecular ring or hexagon units), (*c*) *ad hoc* distributions of specific components.

The repeat unit along the fibre axis (if 658 A.) and the intensity distribution of its orders, taken in conjunction with the molecular proportions of the component amino-acids in (wool) keratin, suggests that *spatial distribution and not only relative amount* of the amino-acids is regular; the simplest model to explain it is a multiple-ladder structure, the analysis an extension of that of Shearer[16] for the simplest of long-chain polar molecules (*n*-aliphatic ketones). Consider the properties of an open-chain composite-ladder molecular keratin model, the main rib (polypeptide chain) having side-rungs (component amino-acid residues) distributed along its length, each regularly in its own period. Let the ladder-structure be a 2^M3^N number of residues long (X-rays and elastic properties) and the residues occur in $2^{-m}3^{-n}$ molecular proportions (chemical analysis). The number of a given residue per molecular length is $2^{M-m}3^{N-n}$. Neglecting fine structure of the chain itself, the structure factor of a cell containing one such model molecule is such that only for orders with k indices characteristically related to the particular $2^{M-m}3^{N-n}$ occurring are meridians of any intensity; further, not all these values need occur strongly. The orders appearing and their intensit depend on the scattering weights, periodicit relative phases and average dispersion in the fib axis direction, of the side-rung residues, and also any regularly occurring chain configurational feat that does not conflict with the validity of the 2 relationship. For wool keratin the first four fact can be quite accurately estimated and a fitting soug for any postulated configurational chain feature.

Straightaway, the model needs progressive mo fication to accord with porcupine quill kerat (Unfortunately, adequate chemical analyses are not y available for porcupine quill itself, but the co parative data of Table 2 indicate that probably serious error would be introduced by using t figures available for wool keratin.) First, a sing chain molecule shows 'clashes' in its subperiodicitie the model must then extend from chain to grid scaffold. Again $M-m$, $N-n$ must be positive or zer While the $2^7 \times 3$ and $2^6 \times 3^2$ data are subject t revision, $N-n = -1$: an adjustment with the effec of a triple long-range fold is required. Both correc tions tend in the direction of a cell of probably larg cross-section, as found. Further, symmetry opera tions, for example in a polymolecular cell, an certain regular short-range chain corrugations coul affect the dominant periodicities, and the latte would also introduce additional weighting.

But most important of all to explain are th common broad structure and properties of th keratin-myosin series. The most probable interpre tation would seem to be that chain periodicities which in themselves do not account for the mai similarities of the keratin-myosin series, must b superposed on some skeleton structure based on close-range chain folding for which the general evidence[1,2] is tremendously strong. Such folding would introduc additional weighting, though not necessarily differen periodicities outside the 2^m3^n scheme. In fact, the new α-model does this. Astbury's original chemical

ucture[2] devised to explain the 5·1 A. meridian
d the quantitative relations of the α ⇄ β trans-
mation has been shown by Neurath[18] to leave too
tle room for certain side-chains. The new α-model
s a simple structural basis, the *close-packing of*
le-chains, which results in a square-stepped poly-
ptide chain of unit 5·1 A., thus yielding the strong
eridian reflexion little dependent on side-chain
eighting; that is, on *chemical composition as such*,
t, of course, accounting only for the main X-ray
atures. This structure is stereochemically accurate
d accords with many broad factors: a common
inciple for fibrous proteins, the right density for
lymorphic transitions, a simple intramolecular
ereoisomerism for the α ⇄ β transformation, correct
stances for hydrogen bond backbone linkage
etween adjacent chains, and, of course, a close-
cking of side-chains. In short, along the fibre axis
e probably get a regularly *spaced* grating (period
l A.) with its planes very regularly varying in
flecting intensity over a much larger (658 A.)
eriod. A combination of this main structure and
eriodic fine structure to fit the experimental data
at present under investigation.

Provided the very regular porcupine quill fibre
ructure is not too disoriented by chemical treat-
ent, the work of Speakman[17] on the chemistry
f the cross-links in wool invites the possibility of so
emically weighting selected residues as to promise
eir location by comparative analysis of the varying
tensity distribution in the (0k0) meridian series.
xperiments with heavy metal and other atoms are
progress.

The fine periodicity is necessarily in size and
eflecting power a function of chemical composition.
he inter-linking of the keratin-myosin series thus
epends on the standard skeleton, with the side-
hain positions as sites, or by interchange of chains
r grids—an intramolecular parallel to solid solutions.
eeping in mind the chemical relationships[19], in
-radiograms of the series we would then expect:
) a standard effect on the intensities imposed by
he common configurational feature; (*b*) very
imilar fibre-axis periodicities (~ 658 A. as in quill);
) the dominant (fairly large spacing) reflexions
robably 2^m3^n orders of this; (*d*) the particular
${}^m3^n$ orders similar for the keratin members, with
light intensity variation, but more markedly different
or myosin.

This is largely borne out, as seen in Table 2, which
ives some meridian reflexions obtained for various
-keratin types together with measurements of an
arlier (Astbury) fibre X-radiogram of dried sartorius
uscle (frog) at 50 per cent extension. Especially
or the latter, precision is not sufficient to *determine*
acroperiods, and the strong 5·1 A. lines are taken
s the 128th order. Of the few reflexions that appear
ot to conform, three or four lines of a sharper nature
n muscle (of which myosin is the principal con-
stituent) are just those which clearly can be
ndexed as the chain cross-sectional reflexions of the
atty constituent or the prominent meridian arc
ssociated with collagen.

Analysis proceeding will be reported elsewhere.
What is important is that the keratin-myosin group
f protein fibres is amenable even in detail to search-
ng X-ray methods; that the new information
lready obtained for α-keratin shows suggestively
imple regularities in accord with those from quite
ther sources; and that the results substantiate and
an now check in detail the new α-model which reconciles the broadest of protein characteristics and, while specific enough for quantitative treatment, is simple and accommodating in detail, as, of course, the biogenesis of proteins demands.

This work is being carried out under the direction of Dr. W. T. Astbury in the Textile Physics Research Laboratories, and under the joint auspices of the International Wool Secretariat and Department of Textile Industries, University of Leeds, to all of whom the writer offers his most cordial thanks.

THE ISLAND OF NEW GUINEA*

By L. Evelyn Cheesman

THIS huge tropical island is only partially explored. Even the coasts are not yet thoroughly and accurately charted, and though there are few large areas of the vast hinterland entirely unknown, only the main topographical features have been named and located in an approximate position. Early records, too, need to be checked; this was proved by one of the Papuan patrols, which found a large lake where the Arthur Gordon Range was supposed to be. The traveller is, therefore, always inadequately equipped for penetrating what is for the most part an exceptionally difficult type of country, whether it be mountains or swamps.

The early geological history of New Guinea can only be indefinitely conjectured since there has never been a general survey. Briefly, it can be summarized thus: Palæogeologists postulate a large land mass, which they named Palæonotis, as having extended from Asia to Australia during the Middle Cretaceous period, and extending as far as New Caledonia, and westward to Sumatra and Java. Some time during the Early Eocene, part of this land broke away from the Australian shelf and later submerged. From this submerged land mass the great folding movements of the Miocene-Pliocene periods raised the high central mountain system of New Guinea. During the next epoch connexion with the Philippines sank, and the island took form as we know it to-day. A more recent connexion with Australia is supposed to have taken place in the Late Pliocene, when the Torres Strait was dry for a relatively short period, allowing the marsupials and other Australian groups of plants and animals to migrate to New Guinea.

It would be thought that geologically young land

* Substance of a Friday discourse at the Royal Institution delivered on May 28.

raised from the sea, its sole continental connexion being with Australia, would possess a fauna and flora basically Australian; also that these would be incomplete with many gaps in the groups. On the contrary, New Guinea has continental fauna and flora, of Asiatic origin, with no serious gaps in the totality of groups such as to suggest population by temporary land bridges. The suggestion is rather that there was connexion with an older fully populated land. There is a strong Australian element, a Malaysian element, and a weak South American element which could have been introduced via Australia.

A possible explanation is to be found north of New Guinea, where are remnants of very ancient mountain ranges, some of pre-Cambrian rock, on an alignment parallel with that of the main ranges. These are: the west coast of New Britain, the Finisterre and Torricelli Ranges, Mt. Oinake, the Cyclops Range, Japen and Waigeu Islands. Supposing these to be part of an old land mass, populated from Asia, which remained above water long enough to colonize the young land of New Guinea as it rose from the sea, this would account satisfactorily for the origin of the Papuasian flora and fauna, which are characterized by a very rich neo-endemism, indicating isolation over a long period.

The Papuasian faunal sub-region includes adjacent archipelagos, the Solomons and New Hebrides archipelagos and New Caledonia.

It is interesting to note in connexion with the above that the Cyclops Range, of very ancient pre-Cambrian rock and old crystalline schists, shows no indication of submergence; no maritime deposits have ever been recorded from the mountains. Another interesting fact emerges from records by geologists of an Australian oil company working in this region for fifteen years, who found evidence of tectonic movements still proceeding in the Torricelli Range.

Reef limestone belonging to many periods and exhibiting an endless variety in formation occurs throughout New Guinea from the coast to high mountains. The formidable "limestone barrier", crossed by Karius and Champion in 1928 between the sources of the Fly and the Palmer Rivers, is described by them as consisting of series of pits of varying sizes, some as much as 100 ft. in circumference, with pinnacles and knife-edged ridges between them. What is probably a similar type of formation appears on Waigeu and also on Japen. On the former island, series of small narrow ranges of about a thousand feet in height have built up the eastern shore of Mayalibit Bay. Between these ranges are very deep clefts almost to sea-level, the ridges are castellated, of rough sharp-edged rocks, with deep pits between the peaks—most dangerous to negotiate especially when screened by vegetation.

Sea erosion produces curious three-sided cylindrical clefts in limestone cliffs, as on the north side of Oinake Massif on the boundary between Dutch and British Territories. One example on Djoea Bluff between 200 ft. and 300 ft. high pierces a cliff to the beach.

Volcanic intrusion occurred in the north of New Guinea; a few volcanoes are still active on the coast. In 1933 a violent earthquake wrecked the Torricelli Range. This ranks with the world's most severe earthquakes. So late as 1939 the northern slopes were still bare precipices, quite an arresting sight in that luxuriant forest; valleys were still choked with rocks, rivers were forming new channels, and huge tree trunks, still standing, have been split a twisted in a peculiar fashion as if wrenched by giant fist.

There is not so much variation in temperature might be expected; the thermometer registers 74 84° F. up to an altitude of 3,000 ft. Above this t temperature falls a few degrees; 38° at night h been recorded at 10,000 ft. On the highest mou tains, 16,000 ft., snow and frost occur. Carste Top, 15,709 ft., has large glaciers.

Rainfall is extremely heavy over nearly all t island, but varies very greatly in localities. The are two seasons marked by the north-west and sout east monsoons. Dry areas or savannahs wi characteristic vegetation occur contiguous with hig rain forest. They are accounted for by the alignme of mountain ranges. Where strong rain-laden win blow parallel with ranges, areas on each side a drier, and where high mountains obstruct the passa of these winds, there is a very heavy rainfall. Thu Port Moresby at the end of one savannah has a annual rainfall of 32 in., while the governme station of Kikori at the farther end among hig peaks has 232 in.

The savannahs are distinct from areas deforeste by natives to make their villages, on which a secon ary vegetation replaces the forest, principally plants and trees of rapid growth, and species with very wide distribution. There are many such area especially on mountains where a large native popula tion has flourished, which has either died out o moved to another locality. Even the alpine grasslan of high mountain tops where are no native village is disturbed by human agency, being often partiall destroyed by the fires of native hunters.

New Guinea is fortunately outside the cyclon zone, but is subject to very high winds, gales, squal and cyclonic disturbances. In Papua occur sudde very violent squalls known as *gubas*. In Netherland New Guinea in the first week of October, gales fro the north-west called *wambrau* blow with terrifi force for eight or ten days, after which they subsid as suddenly as they began. It is an uneasy experienc to be among the mountains during this period Hundreds of trees are blown down; there is n adequate shelter from torrential rain except roc caves, for the rain is driven horizontally. Nothin can be seen but steamy white clouds being carrie by with an amazing velocity, or the grey, drivin sheets of rain. Coastal tribes recognize by certai signs, such as brilliant sunsets, the approach of th *wambrau*; canoes race to shelter and are drawn u on beaches. The south-east of New Guinea does no experience these gales, but apparently (according t verbal reports) they are felt at the same date nort of the Papuan Gulf, and they probably blow acros a wide zone of the centre of the island except wher high mountain masses intervene.

The native population is Papuan-Melanesian characterized by stiff, kinked hair, which gave the the early name of Papoo, that is, "fuzzywigs" Several influences can be detected which result in considerable variation in build, skin colour, an facial features, as well as character of the hair, whic is fine and straight or waved in true Melanesians an Malaysians. In some tribes the skin is definitel lighter in colour, with a bronze tint.

True pigmies exist, mainly in high mountai regions, where they are thought to have taken refug from stronger, aggressive tribes. In certain district are small Negritto-Papuans, resulting from som crossing of types not clearly understood, and presenting variations in size of adults even in one family.

Within the last ten years, gold prospectors made discoveries of densely populated areas in the highlands of the Mandated Territory which had always been supposed to be sparsely inhabited. These tribes had evolved an extremely interesting and advanced type of agriculture.

Head-hunting and cannibalism certainly are still practised, but such customs are becoming rarer. As Papuans come in contact with more advanced peoples, public opinion among themselves is apt to change, and such barbarous practices are deprecated and will finally be voluntarily abandoned.

All Papuan tribes fall into two categories, they are either people of the forest or people of the sea. From babyhood they are taught to observe every landmark, changes in the sky with nuances of which we are scarcely conscious; all have distinctive names, as also all living things however small. Frequently there are different names for the two sexes, even of insects. Sea people are as unhappy when away from the coast and as terrified of mountains as forest people are unhappy in coastal areas and terrified of the sea.

With its rich tropical vegetation, New Guinea is surprisingly poor in natural products to support human life. The indigenous population flourishes only where animal or fish diets are plentiful. Some tribes appear under-nourished. Among vegetables cultivated in native gardens the introduced sweet potato is of good food value; the same cannot be said of other roots, taro and yam. Sweet potato alone can sustain white men in good health; this was proved by Champion and Anderson in the Bamu-Purari Patrol, 1936. Sago, which is the main food of many tribes, is not a white man's diet; it is indigestible and has no energizing value; this was proved by the Karius-Champion Patrol of 1928.

Papuans are extremely primitive, with a Stone Age mentality. Individuals exhibit a marked intelligence, but few outside influences appear to make lasting impressions. When working with white men, opportunities for mastering machinery or for learning storekeeping, mining, etc., may arouse latent ambitions, and the Papuan proves reliable and independent, although in most cases his acquirements are parrot-wise without undue reference to his reasoning powers. For the Papuan exists almost entirely subconsciously; his entire being is not only associated but also closely interlocked with all objects—human, superhuman, animate and inanimate—which compose his natural surroundings. His instinctive reactions to his outside world are scarcely comprehensible to those guided by reason; his power of self-suggestion is unbridled, so that death may be caused by a paroxysm of fear of something entirely imaginary. Control of his own vitality exists to an astounding degree. This mental attitude of Papuans must be realized by those who have any dealings with them, for thus many tragedies may be avoided. Belief in the supernatural is fundamental; it cannot be eradicated; and no other beliefs are sufficiently interesting and stimulating to be substitutes.

Scientific collections from New Guinea have been augmented of late years, due to the efforts of scientific societies and of individuals. Most valuable collections have reached the United States from the Richard Archbold Expeditions, particularly from the latest, 1937–38, when systematic collecting was carried out at different altitudes on the highest mountains of Netherlands New Guinea. A flying-boat is used as transport on these expeditions. Air transport is undoubtedly the solution to all difficulties of collecting on that island, and where the financial aspect need not be considered, should definitely be adopted.

NEWS and VIEWS

Royal Society of Arts : New President

DR. EDWARD FRANKLAND ARMSTRONG has been elected president of the Royal Society of Arts, of which he has acted for a number of years as treasurer. Dr. Armstrong is highly qualified to occupy this distinguished position, for he is a man who has not only made valuable contributions to scientific research in many fields of pure chemistry, both organic and physical, but has also held many high positions in the world of industrial chemistry, where his influence and guidance have led to important advances. As one of the small band of men who worked with the great van't Hoff during his sojourn in Berlin, Dr. Armstrong was successful in clearing up the phase transformations and equilibria of calcium sulphate and its hydrates, a problem which had greatly puzzled van't Hoff and some of his earlier collaborators.

During the period (1915–19) when Dr. Armstrong was managing director of Joseph Crosfield and Sons at Warrington, he carried out in collaboration with his chief chemist Hilditch (now Campbell Brown professor of industrial chemistry at the University of Liverpool) an important and pioneering series of researches on the catalytic hydrogenation of oils and fats. He has also done valuable original work in the field of carbohydrate chemistry, and is the author of well-known monographs on the simple carbohydrates and the glycosides. Apart from the numerous high industrial and administrative positions which he has held, his wide experience as president of the Society of Chemical Industry (1922–24), chairman of the British Association of Chemists (1926), chairman of the Association of British Chemical Manufacturers (1930–33), and chairman of the British Standards Institution (1934–35) will be of great value to the Royal Society of Arts.

Royal Society of Edinburgh: Honorary Fellows

THE following have been elected honorary fellows of the Royal Society of Edinburgh:

Foreign Fellows: Prof. G. D. Birkhoff, professor of mathematics, Harvard University; Dr. H. S. Gasser, director of the Rockefeller Institute, New York; Dr. D. Emilio Jimeno Gil, rector of the University of Barcelona; Prof. Thore G. Halle, Naturhistoriska Riksmuseum, Stockholm; Prof. H. S. Jennings, Walters professor of zoology and director of the

Zoological Laboratory, Johns Hopkins University; Prof. P. Karrer, professor of chemistry and director of the Chemical Institute, Zurich; Prof. O. Veblen, professor of mathematics at the Institute for Advanced Study, Princeton.

British Fellows: The Right Hon. J. C. Smuts, Prime Minister and Minister of External Affairs and Defence, South Africa; Prof. H. F. Baker, emeritus professor of geometry and astronomy in the University of Cambridge; Sir Joseph Barcroft, emeritus professor of physiology in the University of Cambridge; Sir Lawrence Bragg, Cavendish professor of experimental physics in the University of Cambridge.

University of Birmingham

At the annual degree congregation of the University of Birmingham, the Chancellor (Viscount Cecil) conferred the honorary degree of doctor of laws on Dr. Benes, President of the Czechoslovak Republic, Mr. J. G. Winant, American Ambassador to Great Britain, Mr. R. G. Casey, Minister of State in the Middle East, Sir Edward Appleton, secretary of the Department of Scientific and Industrial Research, and Dr. H. R. Ricardo, a pioneer in the development of the high-speed internal combustion engine. In introducing Mr. Winant the Public Orator said: "What is clearest in these dubious times is that in international conflict his country and ours stand for the same things and stand or fall together. We shall not fall. This University has not fallen but is still working on, diminished but not brought low, making light of scars upon her buildings. Her desire is to see Americans and British continuing to work together, mix together, in time of peace as they are so freely doing in time of war, and from this hour to be mixed up herself, as inextricably as possible, with Mr. Winant, with the American universities and with the entire people of the United States".

Mr. Winant, in a short address, said: "We need opportunity for an education which includes understanding of one another if we are to be far-sighted and if we are to see friendly but distant lands. We have a shortage of teachers throughout the world to-day, and yet I believe we have new techniques which would help in that situation if we put our minds to it. The international picture language of Isotype and documentary films, the tactile aids to instruction, which have been evolved in the work of nursery schools, are examples. All of them have this in common: they operate through the medium of a common language, the language of eye and touch. Such new instruments of education—which may well mark an advance of human enlightenment without parallel since the invention of printing—are international in scope. Mass production can provide a system of education by the universal picture language of Isotype, or by the international picture language of the documentary film, at once attractive and, as such, capable of creating its own demand, suitable for use by people who speak different tongues, and equally adaptable to the re-education of those who have been indoctrinated with the Nazi virus and to our own needs, if we envisage the problem of re-educating Fascist youth as part of the wider problem of our common re-education to the tasks of the century of the common man. You can do a great service in Birmingham University to all mankind if you make these new tools available so that we can this time finish the job."

Ministry of Food: Cereals Research Station

The Ministry of Food has, by arrangement with the Department of Scientific and Industrial Research and the flour milling industry, taken over for the period of the War the extensive laboratories at St. Albans which were previously occupied by the Research Association of British Flour Millers. The Ministry will have the advantage of the use of these laboratories and the existing staff for the consideration of all food research problems, but they will continue to be used in the main for specialized work connected with cereals and cereal products. The laboratories will, in future, be known as the Cereals Research Station of the Ministry of Food. Dr. P. Moran, who was previously director of research to the Research Association of British Flour Millers, has been acting as deputy scientific adviser to the Ministry since June 1940. In March last he was appointed, in addition, director of research in the Ministry of Food. In this latter capacity he will direct the work at St. Albans. From June 1, the date on which the transfer took place, the entire control and direction of the laboratories passed to the Ministry of Food.

The Solar Corona and Geomagnetism

The recurrence of certain terrestrial magnetic storms at intervals of 27 days (the sun's rotation period) without any disturbance being visible on the sun's disk has long been an outstanding puzzle of solar physics. Observations of the chromosphere in monochromatic light have established a close connexion between the chromospheric eruptions responsible for short-wave radio fade-outs and certain of the great sporadic magnetic storms, which tend to occur about a day after the visible flare; but the recurrent storms seem as unconnected with chromospheric activity as with photospheric. A recent observation by Waldmeier (*Z. Astrophys.*, **21**, 275; 1942) throws light on this subject. By coronagraph observations at Arosa he has found that certain regions of the solar corona ("*C*-regions") exhibit temporary bursts of activity characterized by abnormally high intensity of the coronal line at 5303 A. The appearance of these areas at the sun's edge is often followed, or preceded, according as the region is being carried in front of or behind the disk by the solar rotation, by magnetic activity on the earth, the time interval being about 7 days (roughly a quarter period). The *C*-regions are very long-lived compared with chromospheric eruptions (at least 24 days as against about an hour). They are confined to the spot zones and seem to exhibit the 11-year periodicity in their frequency of occurrence. If further observations should confirm the connexion between magnetic storms and the central meridian passage of these active zones in the corona, it would seem that both *C*-regions and chromospheric eruptions must emit corpuscles, roughly radially and at speeds up to about 1,000 miles per second, throughout their life-times of the order of a month and an hour respectively.

Statistics of Public Opinion

Public opinion research may be considered to have started with Dr. Gallup, who predicted the voting in the presidential election in the United States of 1936 with an error of only 6½ per cent. For later elections the error has been reduced to 2½ per cent. His method is to choose a sample of about 30,000, which is divided up for age, income, sex, and geographical location in the same proportions as the total population of the United States. Similar predictions are made for local elections in Great Britain by the British Institute of Public Opinion, using a sample of 1,500–2,000. The procedure seems very satisfactory for forecasting election results, but for estimating public opinion on such questions as confidence in the Government, statistical methods may be very misleading. In a paper entitled "The Limitations of Statistics in the Field of Public Opinion Research", read before the Manchester Statistical Society on April 14, Mr. J. G. Ferraby argues that for many purposes the qualitative methods adopted by Mass Observation are preferable. These rely largely on a panel of voluntary observers, who answer written questions drawn up by headquarters, keep diaries, forward letters received by them which comment on general topics, and report conversations, including some not intended to be overheard. It is claimed that this method subordinates accuracy of detail to accuracy in presenting a true picture of the whole. It is not explained how the accuracy of the observers or the truth of the picture is checked.

Earthquakes Registered at Kew and Stonyhurst

SEVEN strong earthquakes were registered at Kew Observatory during the month of May 1943. The first was on May 2, recorded at 01h. 10m. 17s. U.T., and has been reported as having been felt in Württemberg in Germany. The second, also on May 2, began recording at 17h. 30m. 11s. U.T. from an epicentre some 8,700 km. distant, and attained a maximum ground amplitude of 180 μ at Kew at 17h. 58m. 23s. U.T. The third, on May 3, began recording at 02h. 13m. 01s. U.T. from an epicentre some 11,000 km. distant, and attained a maximum ground amplitude at Kew of 200 μ at 03h. 03m. 15s. U.T. The fourth, not so large, was recorded at 09h. 15m. 54s. U.T. on May 20. and the fifth, on May 22, recorded at 22h. 10m. 37s. U.T., has been reported as having been felt in Italy. The sixth was by far the largest of the month. It was recorded at Kew at 23h. 21m. 54s. U.T. on May 25, and from the provisional interpretation of the record came from an epicentre some 12,500 km. distant. It attained maximum ground amplitude at Kew of 340 μ. At Stonyhurst the shock was also recorded at 23h. 21m. 54s. U.T. on May 25, and from a tentative interpretation of the record, came from an epicentre some 105° distant. The seventh earthquake was recorded at Kew at 00h. 27m. 01s. U.T. on May 28, and attained a maximum ground amplitude at Kew of 35 μ. It appeared to come from an epicentre somewhere near the one first recorded in the month. This shock was also recorded at Stonyhurst at approximately 00h. 28m. 20s. U.T. The German radio reported an earthquake at about this time, the epicentral region being west of Balingen near Stuttgart. Some roofs and chimneys are stated to have collapsed, causing injuries to people, and "strange glows" are reported to have been observed. The shock was also reported felt in Württemberg and Baden, in Oberade, the Bodensee and in Alsace. Tremors were felt in Switzerland, most strongly in the cantons of Schaffhausen and Thurgau. The earthquake was apparently preceded by a foreshock, which was felt at places in south-west Germany including Frankfort-on-Main ; but this foreshock was not recorded with any intensity in England. The main shock was also recorded at West Bromwich, on the seismograph belonging to Mr. J. J. Shaw.

The Franklin Institute : Medal Awards

THE following medals of the Franklin Institute, Philadelphia, were awarded on April 21 : *Franklin Medal and Honorary Membership* to Prof. Harold C. Urey, professor of chemistry in Columbia University, for his discovery and production of heavy hydrogen, which has proved of immense importance in furthering research in chemistry, physics, and biology ; and to Dr. George Washington Pierce, for his development of "electrically squeezed" quartz crystals used to narrow the range of radio frequencies. The use of this principle in obtaining accurate oscillations has facilitated the construction of the most precise electric clocks. *Elliot Cresson Medal* to Prof. Charles M. Allen of Worcester Polytechnic Institute. His contribution to the field of hydraulics is a more rapid method of measuring the flow of water by adding a known amount of salt to the water and noting the time required for it to pass electrodes inserted in the pipe lines down-stream.

Howard A. Potts Medal to Dr. Don Francisco Ballen for restoring a valuable natural resource of his country to productivity ; and to Dr. Paul R. Heyl of the National Bureau of Standards for his theoretically important formula to determine the constant of gravitation. *Frank P. Brown Medal* (for achievements in building and allied industries) posthumously to Mr. Albert Kahn, Detroit architect. *Edward Longstreth Medals* (jointly) to Mr. Robert Griffin De La Mater and Mr. William Schwemlein. Their design and successful application of a fluid brake has made practical the drilling of wells to great depths, with increased safety to life and property. *John Price Wetherill Medal* to Robert Howland Leach. *George R. Henderson Medal* to Harry Miller Pflager, senior vice-president of the General Steel Castings Company. *A Certificate of Merit* to Carl S. Hornberger. The 1943 *Louis Edward Levy Medal* (for the best paper published in the *Journal of the Franklin Institute* during 1942) to Anders Henrik Bull of Forest Hills, N.Y., for his paper, "Soil Pressure Distribution along Flexible Foundations".

Institution of Electrical Engineers

IN collaboration with the British Red Cross Society arrangements were made by the Institution of Electrical Engineers for British prisoners of war in Germany to sit for the associate membership examinations held in May and November, 1942. There were nineteen such candidates who took the examination, or parts thereof, on one or other of the two dates, seven of whom were successful in passing Parts I and II, three in passing Part I only, and one Part II only. Five others passed in single subjects, a special concession having been granted to prisoners of war to take one subject at a time if they so desired. A commendably high standard of marks was reached by the candidates. Seventeen candidates in Germany entered for the May 1943 examination.

ASLIB Training Course in Special Librarianship

OWING to the fact that many skilled and experienced librarians have been called up for various forms of national service, there is now great difficulty in operating special libraries and information bureaux to the required standard of efficiency with the untrained and inexperienced assistant staff available. To meet this difficulty, the Association of Special Libraries and Information Bureaux (ASLIB) organized an emergency course of training during the spring of 1943. This has proved to be such a success that the course is being repeated in the autumn and, in addition, an intensive course is being given as a week's summer school (August 9–14) for those who, because of distance or other reasons, cannot attend weekly lectures. The fee for the course is five guineas. Applications to attend should be made as soon as possible to ASLIB, 31 Museum Street, London, W.C.1.

Summer School in X-Ray Crystallography

A SUMMER school in X-ray crystallography applied to industrial problems is being arranged by the Departments of Physics and of Mineralogy and Petrology in co-operation with the Board of Extra-mural Studies of the University of Cambridge, and will be under the direction of Dr. W. A. Wooster, University lecturer in the Department of Mineralogy and Petrology, and of Dr. H. Lipson, assistant in experimental research in crystallography. The number of practical applications of X-ray crystal analysis in industry has greatly increased, and it is quite probable that the usefulness of X-ray crystallography in the solution of industrial problems is not fully appreciated by technical men attached to industrial organizations. There is a growing need for the proper training of such technical men in this type of work, even though a working knowledge of it may have been acquired already. The chief aim of the summer school will be to give a training in the fundamentals of the subject, to bring workers into touch with the wide range of methods used, to teach them the newest techniques, and to indicate the many types of industrial problems in which this work can be used with advantage. Emphasis will be laid on practical work both with apparatus and in the interpretation of various kinds of X-ray photographs. The course is designed to extend from September 6 until September 18, but it will be possible to attend for either week only. In view of the present shortage of staff, apparatus and materials, the numbers attending the school will be limited; application to attend must be made before July 26. Further information can be obtained from the Secretary of the Board of Extra-mural Studies, Stuart House, Mill Lane, Cambridge.

University of London

THE title of professor emeritus of the history of medicine in the University of London has been conferred on Dr. Charles Singer on his retirement from the professorship of the history of medicine at University College.

The degree of D.Sc. has been conferred on Mr. F. R. Goss (Imperial College of Science and Technology); Mr. S. H. Harper (Imperial College of Science and Technology); Miss Emmy Klieneberger (Lister Institute of Preventive Medicine); Mr. W. T. Russell, a 'recognised teacher' at the London School of Hygiene and Tropical Medicine; Mr. T. E. Wallis, reader at the College of the Pharmaceutical Society, London.

Physical Society: Charles Chree Medallist

THE Charles Chree Medal and Prize are provided by the income from a fund given to the Physical Society in 1939 by Miss Jessie S. Chree, of Edinburgh, in memory of her brother, Dr. Charles Chree, a former president of the Society and superintendent of the Kew Magnetic Observatory. The Prize and Medal are awarded biennially in recognition of distinguished research in terrestrial magnetism, atmospheric electricity or cognate subjects, in which Dr. Chree was specially interested. The Council of the Society made the first award to Prof. Sydney Chapman in 1941 for his work in the first of these fields. The Medal and Prize for 1943 have been awarded to Prof. (now Brigadier) Basil F. J. Schonland, director of the Bernard Price Institute of Geophysics, Johannesburg, in recognition of his valuable researches in the second field (see NATURE, February 20, p. 218). The presentation will be made at a meeting of the Society at the Royal Institution on July 16, when Brigadier Schonland will deliver the second Charles Chree Lecture, taking as his subject "Thunderstorms and their Electrical Effects".

Announcements

IN accordance with the terms governing the appointment of the Parsons Memorial lecturers, the lecture for 1943 is to be given under the auspices of the Physical Society. It will be delivered early in the autumn by Lord Rayleigh. The date and further particulars will be announced in due course.

THE governing body of the Imperial College of Science and Technology has elected to Imperial College fellowships the following old students of the college: Dr. F. W. Lanchester, Dr. J. G. Lawn, Dr. F. C. Lea, Mr. F. Twyman, and Mr. H. G. Wells.

DR. R. R. MIMMS has been appointed lecturer in physics in the University of Birmingham to succeed Dr. Guy Barlow, who is retiring after forty years service. Dr. P. B. Moon has been given the title of reader in atomic physics.

THE University of Aberdeen has conferred the honorary degree of LL.D. on Prof. D. M. S. Watson, Jodrell professor of zoology and comparative anatomy, University College, London. The degree of D.Sc. has been awarded to W. Burns, for a thesis on "An Oscillographic Study of the Activity in Nerves associated with the Viscera"; and on Dr. R. D. Stuart, for a thesis on "A Study of Leptospirosis in the South-West of Scotland with special reference to Laboratory Investigation, Epidemiology and Specific Prophylaxis".

DR. W. E. LE B. DIAMOND, assistant secretary of the Institution of Gas Engineers since 1937, has been appointed general manager of the British Plastics Federation.

APPLICATIONS for the conditions of the competition for the Jones-Bateman Cup offered triennially for original research in fruit culture which has added to our knowledge of cultivation, genetics, or other relative matters, may be had on application to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, London, S.W.1.

Biological Research in the West Indies

At present, considerable interest is being evinced about development of the Colonies of the British Empire, particularly the West Indies. Plans have been, and probably still are being, made for utilizing the resources of the West Indies.

In 1939 I had the privilege of leading a strong scientific expedition to Jamaica and I returned with an idea which was shelved with the advent of war. In view, however, of the active developments now taking place, it would seem a proper moment to translate the idea into words. The Imperial College of Tropical Agriculture in Trinidad provides all that is required for training purposes in agriculture, forestry and animal husbandry, but the College is not intended to provide extensive facilities for general research in pure botany and zoology. A marine station exists in Bermuda, but it has, I believe, been closed for some years. In addition, there is the Carnegie marine station in the Tortugas, and a station under the control of Harvard University in the Panama zone.

The West Indies in peace-time are about our most accessible sub-tropical Colony, with a good service of boats and an excellent climate. The building of a tropical research station in this part of the globe would seem to be long overdue. At present most of the research work is being carried out by scientific workers from American universities, and while it may be agreed that the Caribbean is more truly their province, nevertheless the British West Indies look to Great Britain as their fountain-head. The present position, therefore, has many features which are to be deplored; but I believe that they could easily be rectified.

The proposed scheme envisages the building of a tropical research station in Jamaica, which it is hoped would be financed and controlled by a joint committee drawn from the staffs of British universities. The essential part of the scheme is the provision of special facilities and courses for undergraduates from any of the British universities. These courses would have to take place during the long vacations. It is hoped that shipping companies would provide concessions for such parties of students. Arrangements could also be made for members of the permanent staff to exchange for a year with biological lecturers from contributing universities, to the mutual advantage, it is hoped, of both. The station would have to combine research with teaching, and the staff would therefore be under an obligation to assist any of the West Indian schools. Courses comparable to those at Plymouth, Port Erin, Millport, would be arranged for senior schoolchildren during the shorter holidays at Christmas and Easter.

The research programme of the station would deliberately avoid problems in agriculture or animal husbandry, though it would certainly include fishery problems. The staff would be expected to devote themselves to research in pure botany and zoology: numerous problems are available in both these subjects. The proposed station could be described most satisfactorily as a combination of the marine laboratory at Plymouth and the botanical research station at Buitenzorg.

In order to provide the fullest possible scope both for research and teaching, it is suggested that the station be built in two parts, one part up in the Blue Mountains, perhaps on the disused site of the Cinchona station, or in the gardens at Castleton, while the other part would probably be best sited at Montego Bay or on the Pallisadoes. The mountain station would be under the control of a botanist and the lower one under the control of a zoologist. The distribution of staff might be arranged in the following manner:

Mountain station: Botanical director, entomologist, zoologist (reptiles and amphibians) and geneticist.

Lower station: Zoological director, oceanographer, algologist, marine zoologist and fishery expert.

In addition, there might be a floating staff consisting of a geologist, ecologist, mycologist, plant systematist, physiologist and experimental zoologist who would work at either station depending on their current problems. The number of these required would depend upon the scientific interests of the two directors.

It would be desirable for the Hope and Castleton gardens to come under the control of the botanical director, subject to the approval of the Government of Jamaica.

It is fully realized that this scheme is ambitious, and even if it is approved and started the complete staff might not be available for some time. In extenuation it may be pleaded that boldness at the outset is more likely to secure ultimate success. It might prove desirable that the Government of Jamaica, acting directly or indirectly, should contribute financially, but a fundamental part of the scheme is control by the British universities committee. Further discussion might indicate a desire from some of the Canadian universities to co-operate, and there are other details that remain to be worked out. The station is not intended to be a small technical university, nor is it meant to compete in any way with the Imperial College of Tropical Agriculture in Trinidad. A close liaison would inevitably exist between the station and the Institute of Jamaica.

The provision of such a station would give a great stimulus for research in the Caribbean and also at the same time an opportunity for future generations of scientific workers from the British Isles, Canada and the West Indies, to obtain at first hand knowledge of plants and animals which at present can only be provided by text-books.

Universities and Government are unlikely to approve finance for such a scheme at present, but if approval in principle is now given the details could be worked out and erection of the station could commence at the first favourable moment.

Ribonucleic Acids in Animal Tissues

The original view that ribonucleic acids (yeast nucleic acid, phytonucleic acid) are to be found exclusively in plant tissues, and desoxyribonucleic acid (thymonucleic acid, animal nucleic acid) exclusively in animal tissues is now known to be no longer tenable.

Apart from the ribose mononucleotides and dinucleotides which are known to play an important part in the metabolism of animal cells, ribopolynucleotides (nucleic acids) have been detected histochemically in animal tissues[1], and one such ribonucleic acid has been isolated from mammalian pancreas[2]. Moreover, desoxyribonucleic acid has been reported in yeast cells[3] and in plant tissues[4]. Both types of nucleic acid are present in bacteria[5].

Evidence is accumulating that both in the plant cell[6] and in animal cells[7] desoxyribonucleic acids are to be found in the nucleus and ribonucleic acids mainly in the cytoplasm. Ribonucleic acids may also form, especially in active cells, a small proportion of the nucleic acid of the nucleus[8] where thymonucleoprotein associated with the structure of the chromosomes predominates[9]. The nucleolus is composed of ribonucleoproteins[10] and is claimed to be associated actively with the synthesis of the cytoplasmic ribonucleic acids or nucleotides which are especially abundant at the nuclear membrane. These ribonucleic acids may also form part of the mitochondria[11], which appear to be phospholipid-ribonucleoprotein complexes. Such complexes of phospholipid with nucleoprotein containing ribonucleic acid are found in adult liver[11], in normal embryonic tissue[12], in embryo and adult brain[13], in equine encephalomyelitis virus[14] and in the active fraction of tumour-producing sarcoma extracts[15].

The biological activity of the ribonucleic acids has also been emphasized by their presence in plant viruses such as tobacco mosaic virus[16] and in the tissue growth-promoting factor of embryo juice[17], and by recent reports of high concentrations of ribonucleotides in the cytoplasm of cells in which rapid protein synthesis is taking place[10], including embryonic tissues, in tumour tissues[18], in the cytoplasm of proliferating and differentiating cells exposed to X- and gamma-radiation[19], and in the intercellular fluids from injured cells[20].

We have recently demonstrated, using chiefly tissues from the adult and embryo sheep, that ribonucleic acids (ribopolynucleotides) are widely distributed in surprisingly high concentrations in mammalian tissues. After removal of lipoid and acid-soluble phosphorus (including simple nucleotides), the tissue residue was extracted with cold and then hot 10 per cent sodium chloride to remove the nucleic acids, which were then precipitated as lanthanum salts and the precipitate analysed for pentose and desoxypentose. As evidence based on pentose estimations alone may not be in itself conclusive, the occurrence of ribonucleic acids has been confirmed enzymatically by treating portions of the sodium chloride extract with crystalline ribonuclease[21], which attacks ribonucleic acids only, and estimating the amount of nucleic acid phosphorus split off by the enzyme.

As the accompanying table shows, in most cases the total nucleic acid content, as measured by nucleoprotein phosphorus estimations, is considerably higher in the embryo than in corresponding adult tissues. The ratio of ribonucleic acid phosphorus to desoxyribonucleic acid phosphorus is, however, either of the same order in the embryo as in the adult or is slightly higher in the adult. Although the absolute amount, therefore, of both types of nucleic acid is much higher in most embryonic tissues than in the corresponding adult tissues, in any given tissue the amount of ribonucleic acid relative to the amount of thymonucleic acid remains the same in the adult as in the embryo or may be slightly greater in the adult.

The results also support the view that desoxyribonucleic acids are found in the nuclei and ribonucleic acids mainly in the cytoplasm. The ratio is very low (0·18) in the case of the isolated nuclei of embryo liver. Moreover, saline extracts of minced shee embryo with powerful growth-promoting propertie to fibroblasts cultivated *in vitro* have a much highe ratio (9·1) than any of the individual tissues. Such extracts would be expected to contain cytoplasmic rather than nuclear material[7]. This high ratio may throw light on Fischer's[17] claim that the growth-promoting activity of embryo juice is associated with the ribonucleoprotein fraction.

COMPARISON OF TISSUES OF ADULT SHEEP AND 9–10 WEEK SHEE EMBRYO.

Tissue	Nucleoprotein phosphorus % dry wt.		Ratio ribonucleic acid phosphorus / desoxyribonucleic acid phosphorus in precipitate of La salts	
	Adult	Embryo	Adult	Embryo
Liver	0·25	0·55	3·5	2·5
Lung	0·43	0·76	0·9	0·7
Gut	0·52	0·68	1·0	1·1
Heart	0·12	0·49	2·8	2·8
Spleen	0·60	0·64	0·5	0·6
Kidney (cortex)	0·34	0·65	1·9	1·0
Brain	0·19	0·24	2·1	2·3
Muscle	0·09	0·36	3·6	1·4
Testis	0·42	—	2·6	—
Thyroid	0·10	0·42	2·0	1·1
Thymus	—	1·06	—	0·2
Pancreas (ox)	—	—	8·0	—

The evidence so far obtained indicates that animal tissues in general contain appreciable amounts of pentose nucleic acid (presumably ribonucleic acid) which can act as substrate for the enzyme ribonuclease. Whether its structure is similar to that of the ribonucleic acid of yeast, or more probably to that of the ribonucleic acid of the pancreas, is not yet known.

Our grateful thanks are due to Dr. Kunitz for a specimen of crystalline ribonuclease, and to the Carnegie Trust and the Medical Research Council for grants.

Inhibition of Urease Activity by Ascorbic Acid

ASCORBIC acid has been found to have a marked inhibitory effect on urease activity. With some preparations of the enzyme, the formation of ammonia from urea is completely inhibited by a concentration of one part ascorbic acid in 200,000, and 50 per cent inhibition is obtained with one part ascorbic acid per million. The inhibition is prevented by addition of cysteine.

The urease preparation used was obtained by shaking 0·2 gm. Arlco-Jack bean meal with 18 ml. distilled water and centrifuging. 0·5 ml. of the urease, 3 c.c. acetate buffer *p*H 5·0, ascorbic acid and cysteine hydrochloride added as 0·1 per cent solutions, and water to make a volume of 8·3 ml. were kept at 45° C. for half an hour, and then 1·7 ml. of 3 per cent urea solution added, to give a total volume of 10 ml. The ammonia formed was estimated colorimetrically with Nessler's reagent, using a Hilger 'Spekker' photo-electric absorptiometer.

Mechanism of Polysaccharide Production from Sucrose

IT has been shown that suitable bacterial cell extracts may act on sucrose with formation of a polyglucoside, dextran[1,2], or of a polyfructoside, levan[3]. As instances of enzyme-mediated polymer syntheses *in vitro*, these reactions command wider interest than would necessarily alone be merited by the functional importance of levan and dextran in microbe and plant metabolism. The enzymes responsible for production of levan and dextran from sucrose will conveniently be designated, in accordance with the substrate requirement and reaction end-product of the enzyme agent employed, respectively as levansucrase and dextransucrase. It is the former enzyme, as it appears in autolysate fluid of a selected Aerobacter strain[3], which is the subject of the present communication.

Levansucrase acts on sucrose or raffinose with production of levan and reducing sugar. All other substrates so far tested, including, in addition to common hexoses and disaccharides, several substrates with a terminal fructofuranoside group, namely, Neuberg ester, Harden-Young ester, methyl gamma fructoside, and inulin, failed to support levan production[4].

In its general properties, levansucrase is not unlike an ordinary carbohydrase. Its solutions are stable for months if kept on ice; when boiled they are immediately inactivated. The enzyme shows optimal activity at *p*H 5·5. It develops half-maximum synthesis velocity on sucrose concentrations between 0·02 and 0·06 molarity, the exact point depending on the enzyme lot. Glucose retards levan production to an extent dependent on its concentration relative to sucrose; fructose, on the other hand, is completely non-retarding. Dialysis of the enzyme does not affect its activity as measured in citrate buffer on sucrose.

It has been shown that levan production from sucrose and raffinose can be described by a common formula:

$$(n + m).\text{aldosido} <> \text{fructofuranoside} + n.\text{H}_2\text{O} \rightarrow (m+n).\text{aldose} + n.\text{fructopyranose} + [\text{levan}] \quad . \; . \quad (1)$$

where aldose is either glucose or melibiose, depending on whether sucrose or raffinose is the substrate employed, m and n are whole numbers experimentally determined, and where [levan] represents m residues of fructofuranose polymerized to molecules of levan.

Galactose is not liberated by the enzyme from raffinose concomitantly with levan production. As is implicit in (1), therefore, production of levan from raffinose cannot be regarded as proceeding via intermediately formed sucrose.

The ratio m/n characterizes the synthesizing efficiency of sucrose conversion by the tested enzyme system. Its magnitude varied, depending on the conditions of the experiment and on enzyme lot, between 0·7 and 1·6.

Levan production does not proceed unchecked in the direction indicated in (1). After an initial rapid advance, it is progressively slowed. On adequate sucrose amounts, and using cell-free soluble levansucrase as synthesizing agent, levan production always came to a stop once the concentration of levan was between 300 and 500 mgm. per cent, the value being variable within these limits with enzyme lot. New simultaneous addition of enzyme and sucrose to mixtures in which levan production had come to a stop failed to renew the synthetic process.

It should be observed that the measured end-point is not one of mass equilibrium between the saccharide reactants noted. Increase in the initial concentration of sucrose beyond a necessary minimum does not bring about a shift in the position of the levan end-point. Moreover, reversal of the direction of the enzyme's activity has not so far proved feasible. Although intact cells of the selected Aerobacter strain are themselves able to ferment levan slowly, soluble cell-free levansucrase preparations failed completely to act either on levan alone or on mixtures of levan and glucose in any chemically evident way.

Balance sheet experiments revealed no drop in total carbohydrate content during levan production *in vitro*. Furthermore, known poisons of respiration or of glycolysis, namely, cyanide, fluoride, monoiodoacetate, and phloridzin, failed to suppress or even markedly to retard levan production. One may conclude, therefore, that equation (1) states fully the *net* result of the action of Aerobacter autolysate on sucrose. Conceivably, levan production is linked energetically or otherwise with sucrose hydrolysis, from which, indeed, it has not yet proved separable. Clearly, however, it is not so linked with energy-yielding desmolytic transformations of sugar.

In conclusion, it is relevant to emphasize that the specificity characteristics of levansucrase, as reported above, run counter to the theory of levan production advanced by Hibbert and his school[4]. They fail, in fact, to conform, as will be detailed elsewhere, with any one of the established general systems of carbohydrase specificity[5].

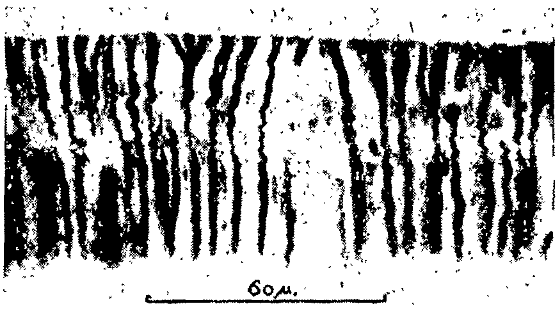
Pore Canals of the Insect Cuticle

IT has been suggested from time to time that the pore canals of the insect cuticle offer an important channel for the entry of contact insecticides, and Wigglesworth[1], working on the bug Rhodnius, in which the canals contain protoplasmic filaments, or perhaps fluid, has recently given additional evidence in favour of this view. But Richards and Anderson[2], as a result of their electron microscope studies of the cockroach cuticle, believe that the pore canals are filled by a watery fluid and not by protoplasm, and that oil-borne insecticides cannot penetrate by this route. Among earlier writers Holmgren[3], Plotnikow[4], and Berlese[5] have expressed the view that although the canals are occupied by protoplasm during early growth of the cuticle, they are later filled by some cuticular substance. If this is so, they would appear scarcely likely to be involved in insecticide penetration.

Although Wigglesworth[6] has rightly pointed out the slender basis on which the theory of cuticularization of pore canal contents rests, consisting of nothing more than the staining of the contents with such dyes as eosin and Congo red, and has shown that on drying the cuticle of Rhodnius the canals become filled with air, I have recently, during a study of the cuticle of Dipterous larvæ, had evidence that in some insects at least pore canals may be transformed into solid structures.

The third-stage larva of *Sarcophaga falculata* possesses pore canals which on account of their large size are readily observed. In an early larva of this stage, they extend completely through the thin (10 μ) endocuticle. They show the tufted form illustrated by Plotnikow[4] for the canals of the caterpillar of *Bombyx mori* and of a Syrphid larva, and stain readily with eosin. In a larva one day older, the canals appear single and almost straight, with no terminal branching, and pass through only about th inner one-third of the now thicker (35 μ) endocuticle Still later, no structures staining with eosin can b detected in the endocuticle, but in their stead rod like bodies with no different staining reaction from the now very thick (60–140 μ) endocuticle are faintly visible.

It seemed probable that these rods are cuticular structures derived from the cytoplasm of the pore canals, and accordingly larvæ of progressively in creasing age were heated with caustic potash, sec tioned, and treated with iodine as a specific test for chitin in the manner described by Campbell[7]. In the early larva, in which the tufted pore canals stain with eosin, *no positive reaction took place*. In larvæ one day older, only the outermost parts of the canals assumed a deep violet, while in the still older larvæ, in which no structures are revealed by eosin, the whole extent of the canal assumed a deep violet coloration, deeper than that of the surrounding endocuticle, and even more indicative of the presence of chitin. The form of the pore canals was thus clearly revealed, as shown in the accompanying photograph.



SECTION THROUGH THE CUTICLE OF THE THIRD-STAGE LARVA OF SARCOPHAGA, TREATED WITH CAUSTIC POTASH AND IODINE TO DEMONSTRATE THE DISTRIBUTION OF CHITIN. THE PORE CANALS GIVE AN INTENSE POSITIVE REACTION.

It appears then that, although chitinization of pore canal contents may take place in some insect cuticles, those who accepted the coloration of the canals with eosin and similar stains as evidence of this were in error. Chitinization of the contents of the canals takes place later than in the stage illustrated by Plotnikow[4], and proceeds inwards from the distal ends of the canals. Whether it takes place by secretion of chitin from the tips of the receding protoplasmic filaments, or by bodily conversion of the filament itself, is not clear.

Further evidence of the solidity of the contents of the canals is provided by splitting the cuticle horizontally into two sheets, when the chitinous strands are clearly visible as solid rods projecting from the inner face of the outer sheet.

The form of the chitinized pore canals is similar to that of the open canals of the cockroach described by Richards and Anderson[2], but differs in showing terminal splitting—a result of the form of the canals of the early larva. In the photograph many of the canals appear unduly thick owing to the tight coiling of the helix. Some fifty to seventy canals are associated with each hypodermal cell, giving a density of distribution of the order of 15,000 per sq. mm. The smaller canals of the cockroach are much more numerous, occurring at the rate of 1,200,000 per sq. mm.

In connexion with the penetration of insecticides hrough the cuticle, one point remains to be menioned. The ease with which the contents of the anals are revealed by splitting the cuticle indicates hat there is no fusion between them and the surounding endocuticle ; indeed there may exist around ach filament a small annular space which might well e involved in insecticide penetration.

In conclusion, it should be stated that the cuticle f the Cyclorrhaphous third larval instar is probably pecialized in connexion with its ultimate conversion nto the puparium, and that chitinization of pore anal contents may not be of widespread occurrence. Nevertheless, a renewed examination of the cuticles f a number of diverse insects would be of interest.

A full account of the work of which these results orm a part will be given later.

The Term *Tractellum* in Flagellate Organisms

In the latest number of the *New Phytologist* an rticle appears under the heading of "Recent Work n Flagellar Movement", by D. Barker of the Deartment of Zoology and Comparative Anatomy, Oxford[1].

Though there is considerable difference of opinion pparently on the structure of flagella or cilia there is now no difference of opinion on one fundamental point, and that is that the waves or disturbances start at the base of the flagellum and not at the tip. This being so there can be no such thing as a tractellum. The whole misconception originated so far as I can gather with the flagellum of *Peranema trichophora* (Ehrbg.) Stein, as described and figured by Verworn[2].

Direct photographic evidence, taken from the high-speed cinema film, that the waves start at the base of the flagellum of Peranema and not at the tip was given in NATURE so long ago as 1936[3]. We know that in all cilia lining epithelial structures so far investigated, and also in the frontal and abfrontal cilia or flagella on the gills of Mytilus or Modiolus, the waves start at the base, and the same is true for all sponges so far as we know. Finally, the same has been shown to be true for more than a dozen different species of flagellates, and there is no direct evidence of it starting from the distal end.

It seems, therefore, highly desirous that the term *tractellum* should disappear from all text-books, elementary or otherwise, until direct photographic evidence of its existence is produced.

In the majority of flagellates the flagellum or flagella are attached to the anterior end of the cell, but to use an apt expression of a colleague, the organism is not *pulled forward by its hair but it is pushed forward by its nose.*

Actually the anterior end of the cell is pushed round by the flagellum and the whole cell thus made to rotate and gyrate about a given axis, and this of itself is sufficient to supply a forward component on the simple mechanical principle of the inclined plane.

How the Sperm Reaches the Archegonium in *Pellia epiphylla*

In text-books on botany *Pellia epiphylla* (L.) Corda is very often chosen as an example of the liverworts, and hence any information about its structure and biology is of interest. It has no doubt been chosen because it has, in comparison with the majority of liverworts, a relatively massive gametophyte and a large sporophyte ; it is also a widely distributed and common plant.

It is usually assumed that the sperm swims by means of its two flagella from the antheridium to the archegonium, which contains the ovum. The archegonia are, however, placed at the apex of the plant and the nearest antheridia are 5–10 mm. distant on the dorsal surface. Showalter has shown that free sperms in a closely related genus (Aneura) may take several hours to spread a distance of 10 mm. In previous investigations[1] it was found that in many mosses and liverworts it was the spermatocytes, each of which contains a single sperm enclosed in a membrane, which were liberated from the antheridia, and that these were carried rapidly by the agency of surface tension over the free water surface at a rate of about 20 mm. per minute.

In June 1943 plants with ripe antheridia were taken and their upper surfaces wetted. The spermatocytes were seen to be extruded in grey masses into the water, and when these reached the surface their spermatocytes were seen to break apart and disperse over the wet surface with great rapidity. The spermatocytes reached the archegonial involucre in about fifteen seconds. It takes about fifteen minutes for the free, swimming sperm to emerge from the spermatocyte, so that from the time of opening of the antheridium only a little more than fifteen minutes would elapse before free, swimming sperms were at the archegonia. If the transport of a sperm from an antheridium to an archegonium depended on its swimming powers alone, it would take several hours for it to reach the archegonium, and in that time the wet surface of the thallus might become dry.

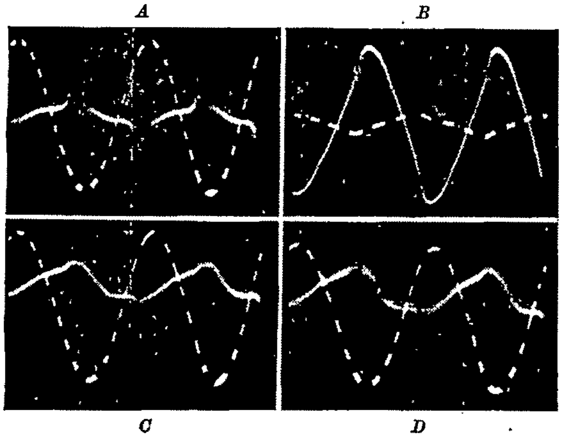
A New Method of Electrical Testing, Applied to Insulated Wires

A DIFFICULTY was experienced recently in carrying out some electrical tests on enamelled wires at temperatures up to about 120° C. Pairs of wires were twisted together in accordance with B.S.

Specification 156, Appendix A, and although it was possible to obtain all the required electrical properties at atmospheric temperatures, this was not so with some classes of enamel when the same tests were attempted in rising temperatures. As changes in power factor were being followed, a relatively high voltage between wires was used (about 1·2 kV.), and it was found impossible to avoid premature breakdown of some classes of enamel when the temperature was raised rapidly. Evidently a means of controlling the voltage applied between wires was wanted so that as the temperature rose, the voltage would fall off; but it was not practicable to do this accurately and quickly enough with ordinary hand control.

Automatic voltage control was satisfactorily achieved by replacing the test transformer then in use by another having an extremely poor regulation. By this means the enamels which had hitherto broken down prematurely caused an increasing drain on the transformer as the temperature rose, this being followed concurrently by a drop in voltage.



By connecting voltage and current leads to a double-beam cathode ray oscillograph with the usual 180° phase shift, it was thus possible to follow changes in power factor with changes of temperature as rapid as 100° C. per second, the required voltage regulation being entirely automatic. Oscillograms *A* and *B* represent conditions at 20° C. and 120° C. respectively, using an enamel sensitive to temperature; *C* and *D* are those for an enamel which shows little sensitivity to temperature. For clarity all voltage curves are shown dotted, and the interchange of current and voltage magnitudes in the former case is thus shown very clearly. The 'haze' at the peaks of the current wave in oscillogram *A* depicts a high-frequency discharge consequent upon the high voltage used, and this is naturally absent in oscillogram *B*, which illustrates a much lower voltage. This high-frequency discharge appears to be a characteristic of those enamels which are sensitive to temperature.

The change from condition *A* to condition *B* is not a chemical one, and on the oscillograph the gradual change from one extreme to the other could be observed any number of times as the temperature was raised and lowered.

Biological Control of the Fly Populatio in Sewage Filters

In his communication on "Town Planning and th Small Sewage Purification Plant", Dr. Lloyd[1] discusses the problem of controlling the numbers of th sewage fly, *Anisopus fenestralis*, in and aroun sewage filters close to housing estates. Thoug Psychoda flies were also present in large numbers i these filters, they apparently caused little nuisanc compared with that from the Anisopus flies, whic entered the neighbouring dwellings in large numbers

For the past two years observations have bee made, as part of the programme of the Water Pollution Research Board of the Department of Scientifi and Industrial Research, of the seasonal variatio in the fly population in large-scale percolating filter at the Minworth works of the Birmingham Tam and Rea District Drainage Board. The results sugges a possible answer to the question raised by Dr. Lloyd

The four filters under observation at Minwort have a varied fauna composed mainly of *Psychod alternata*, *Anisopus fenestralis*, *Achorutes viaticus*, an Enchytræid worms. It was found that unde optimum conditions of growth, *Anisopus fenestrali* took 121, 73, 50 and 39 days at 9° C., 13° C., 18·5° C and 21° C. respectively to complete its life-cycle With a restricted food supply, however, the duratio of the life-cycle may be much longer than is indicate by these figures. Whereas *Psychoda alternata* i restricted to the warmer months[2], the temperatur of the filters is normally favourable throughout th year for the development of Anisopus. The filter therefore carry during the winter months a larg potential population of flies which emerge in th spring if weather conditions and conditions in th filters are favourable. If the surface layers of th filters are open, Anisopus emerges in large number during periods of warm weather in the spring. Th numbers decline in the late spring and early summer when *Psychoda alternata* begins to breed in larg numbers in the filters.

At summer temperatures it appears that *Psychod alternata* is more effective than Anisopus as a scourin organism. Under certain conditions the accumulatio of solid matter in the upper layers of a filter may b sufficient in amount to prevent the emergence o Anisopus without impairing the efficiency of th filter by causing serious ponding on the surface Such conditions may prevail in the spring in filter operated at high rates as alternating double filter with a short period of alternation, or in a filte treating a mixture of sewage and effluent at a hig rate. The emergence of large numbers of Anisopu in the spring is thus prevented. The filters at Minworth became cleared of solid matter by summe owing to the scouring activity of Psychoda. Numerou Psychoda but few Anisopus emerged from thes filters during the summer.

The successful competition of Psychoda wit Anisopus in these filters is a good example of natura biological control, and the observations recorded suggest another line of approach to the problem raised by Dr. Lloyd, which is consistent with th operation of filters at their maximum capacity.

T. G. Tomlinson.

TREATMENT OF CANCER BY FAST NEUTRONS

By Dr. L. H. GRAY

and

Dr. J. READ

Mount Vernon Hospital and Radium Institute,
Northwood, Middlesex

TONE AND LARKIN[1] have recently reported upon their experience, over a period of two ears, in the treatment by fast neutrons of 120 atients with advanced 'incurable' cancer in various ites. The neutrons were generated by the 60 in. yclotron at the Crocker Radiation Laboratory, San rancisco. They were able to demonstrate both linically and pathologically that some tumours disppeared as a result of neutron therapy, and their eport, which is presented with admirable clarity nd restraint, is on the whole encouraging. We wish o comment upon the possible influence of the energy f individual neutrons, both incident and at a depth n the body, on the results obtained.

It has now been established beyond all doubt that he biological effect produced by ionizing radiations lepends not only on the total ionization produced vithin the cell (the tissue dose) but also on the spatial distribution of these ions. The latter parameter may be expressed numerically by the average umber of ions formed per micron of track of the onizing particles within the cell, and varies from 10 n the case of γ-rays to 40 for 200 kV. X-rays, about 00 for neutrons (see below), up to 4,000 for α-particles. (The mean density of ionization along the track of uranium 'fission' fragment is about 130,000; but the biological effects of these particles have not so far been studied, though such experiments seem feasible in certain cases.)

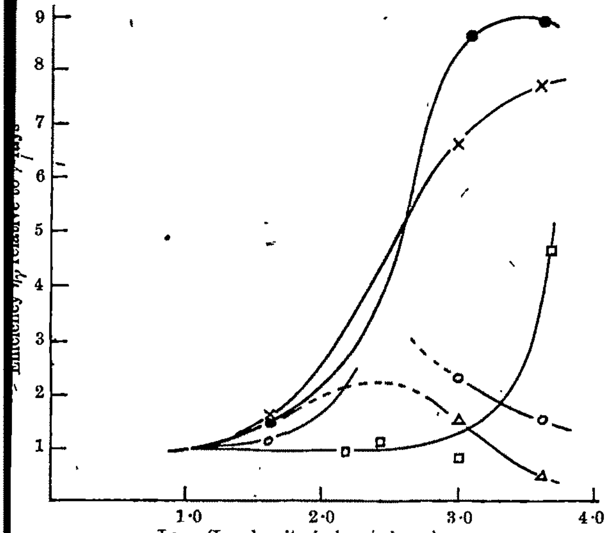

Fig. 1. BIOLOGICAL EFFICIENCY AS A FUNCTION OF LOG$_{10}$ (ION DENSITY).

□ Disinfection of spores of *B. mesentericus* (ref. 9).

○ × Two types of chromatid injury induced in the microspores of *Tradescantia bracteata* by irradiating during prophase. ○ Simple chromatid breaks. × Isochromatid breaks (ref. 14 and unpublished data obtained by Kotval, and Kotval and Gray).

△ Inhibition of mitosis in roots of *Vicia Faba* (Gray, Mottram, and Read, unpublished.)

● Lethal effect on roots of *Vicia Faba* (ref. 18).

Most of the determinations of η are subject to an uncertainty of the order of 10–20 per cent.

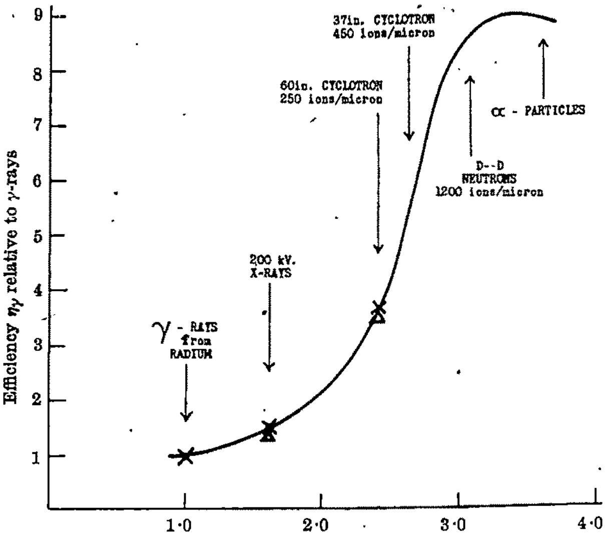

Fig. 2. EXAMPLE OF BIOLOGICAL EFFICIENCY AS A FUNCTION OF LOG$_{10}$ (ION DENSITY).

Full Curve: Lethal action on roots of *Vicia Faba* (Fig. 1 and ref. 18).
Experimental points:

× Skin reaction

$\eta_\gamma^X = 1{\cdot}5$ (ref. 24); $\eta_X^N = 2{\cdot}5$ (refs. 1, 22)

△ Lethal action on tumour tissue irradiated *in vitro*

$\eta_\gamma^X = 1{\cdot}3$ (ref. 23); $\eta_X^N = 2{\cdot}6$ (refs. 19, 22)

We may express the relative efficiency of two radiations A and B in producing a given biological reaction by the reciprocal ratio of the doses necessary to produce this effect and denote it by the symbol η_B^A. (Where published data refer to doses not measured in units proportional to the ionization per unit volume of the cell, allowance has been made for this fact in calculating efficiencies. It has been assumed that 1 n unit = 2·5 energy units[22].) It has been shown that in the case of the production of sex-linked lethal mutations in Drosophila sperm[2,3], the inactivation of a number of viruses[4–7] (under conditions which preclude an indirect action through the ionization of the aqueous medium) and the disinfection of vegetative bacteria (*B. coli*)[8,9], η decreases with increasing ion density. This decrease is capable of a simple quantitative interpretation in terms of the relation between the size of the structure inactivated and the mean distance apart of the ions[5]. On the other hand, there are many cases in which, over the range of ion density investigated, which in some cases is 10–500 ions/micron, and in others 10–4,000 ions/micron, η increases steadily with ion density. These include the production of chromosome aberrations[10–15], the inhibition of hatching of Drosophila eggs[16], the lethal effect on roots and shoots of seedlings[16,17,18], the inhibition of growth of inoculated mouse tumours irradiated *in vitro*[19], the regression of mouse tumours irradiated *in vivo*[20], and numerous other reactions listed elsewhere[21,22].

Fig. 1 shows five examples of the variation of biological efficiency with ion density, of the type under consideration. They have been chosen as being cases in which the same biological material and the same criteria of effect have been employed in irradiations covering the whole range of available ion densities. There is clearly considerable diversity in the effect of changing ion density on different types of biological response—a diversity which goes even deeper than appears from these curves, since the shape of the curve even for the production of a given type of injury in a particular entity, such as a chromosome, is different at different developmental stages in the cell cycle[10-15]. This diversity may at some future time prove valuable as an aid to the analysis of some complex reaction, such as tumour regression, into its constituent factors, but at present we are only at the threshold of a coherent interpretation of these curves. The recent successful interpretation of chromosome break data[14] may provide a starting point.

The data for tumour response are rather fragmentary. The value of η has been measured for the effect of γ-rays, X-rays and fast neutrons on mouse tumour irradiated *in vitro*[23,19,22]. From Fig. 2 it will be seen that within this limited range, tumour response closely follows the course of the curve for the lethal effect on bean roots. Further, it has been found that η_γ^N has a very large value ($\sim$ 20) for the effect of (D–D) neutrons on mouse tumour irradiated *in vivo*[20]. The bean root curve (Fig. 2) may therefore be taken as a rough guide to the probable influence of ion density on tumour response. The mean ion densities of the recoil proton tracks from neutrons generated in several ways are indicated on the figure. It is clear that these neutron beams may be expected to differ considerably in biological efficiency.

The successful treatment of a tumour does not depend on a single biological effect, but on at least two effects, the tumour reaction and the normal tissue reaction, and possibly on others.

Stone and Larkin[1] formed an estimate of the relative effectiveness of neutrons and X-rays for one important normal tissue reaction, namely, the production of a given degree of erythema of the skin. The corresponding value of η has been plotted and lies close to the same curve (Fig. 2). It is interesting to note also that they observed less severe skin reactions than expected when changing from treatment with the 37-in. to the 60-in. cyclotron, but the possibility that the difference lay in the method of dose measurement could not be excluded. Any superiority of neutrons over X-rays, however, may be taken to indicate that η is increasing more rapidly with ion density for the tumour than for normal tissue, and therefore in the light of Fig. 2 we may hazard a guess that if neutrons from the 60-in. cyclotron showed *some* superiority over X-rays, neutrons from the 37-in. cyclotron or (D–D) neutrons would show an even greater superiority. If it is desirable to retain the advantage of the high neutron intensity obtainable from the larger cyclotrons, it might be found to be of therapeutic value to slow down the neutrons somewhat by passage through wax before entering the body.

The optimum neutron energy can, of course, only be found empirically. There is no reason for believing that it will coincide with the neutron energy for which η is maximum for the lethal effect on bean roots. Indeed, should the course of the curve for $\frac{\eta\text{ (tumour)}}{\eta\text{ (normal tissue)}}$ have the shape of Fig. 1, one would probably choose to use neutrons somewhat faster than (D–D) neutrons, so that, as a result of the slowing down of the neutrons in passing through the body, an energy corresponding to the maximum value of this ratio is just reached at the site of th tumour. In this way, for equal physical doses, th skin would be less damaged because exposed to radiation of relatively lower efficiency, and at th same time the tissues deeper than the tumour woul not be excessively exposed.

When a 60-in. cyclotron is used as a source neutrons, it is likely that the skin is in a relativel favourable position, being exposed to very fas neutrons, and that the tissues deeper than th tumour, through being exposed to slower neutron are relatively more damaged (for equal doses) tha the normal tissue at the site of the tumour. This ma perhaps be the reason why Stone and Larkin observe very severe systemic reactions and diarrhœa in patient receiving radiation to the upper abdomen, though th skin, which received a very much larger dose (ionization per unit volume of tissue), was not excessivel damaged.

ULTRA-HIGH ELECTROMAGNETIC FREQUENCIES

AT a joint meeting of the Institute of Radi Engineers and the American Institute o Electrical Engineers held on January 28, G. C Southworth explained how micro-waves are addin to the tools of the communications engineer (*Bel Lab. Rec.*, 21, No. 7; March, 1943). Briefly outlining the conquest of the frequencies, Dr. Southworth mentioned the need of television and communication in general for more and wider channel as one of the prime forces in the advance into th micro-waves. Other desirable features of the 'micro region are the small size of antennæ and their hig directivity, and the fact that the waves follow th line of sight and thus do not interfere with signal beyond their own useful range.

Some method of conducting waves from generato to antenna, and from antenna to receiver, is obviousl necessary. While ordinary insulated wires can b used through the broadcast range and beyond, i the short-wave range special attention must be give to losses in the insulation, to radiation into spac and into nearby conductors, and to the effects o uning produced by stray capacitance and inductance. The coaxial line, in which one conductor is formed nto a tube and the other is enclosed in it, is an xcellent expedient. If the central conductor is ompletely removed, it is still possible to transmit nergy down the tube, which then becomes a wave uide. If the tube is filled with insulating material, ven the outer conductor can be removed. The oaxial and the conducting tube or wave guide are he most promising of these arrangements. Compared from the point of view of attenuation losses, he coaxial line is better at the lower frequencies ; but in the micro-wave region, which is of most mportance at the moment, the wave guide has decided advantages. However, below a certain frequency—about 3 × 10^9 for the wave guide—the wave guide 'cuts off' abruptly.

Wave guides are decidedly useful for conveying micro-waves from their generator to the place where hey will be used. They contain no insulating material and so are entirely immune to moisture, while their waves can be radiated by simply flaring out the tube nto a horn. A wave guide may also be made into a resonant chamber by blocking one end with a metal plate and closing the other partially by a plate with a hole in it. By varying the length of the chamber, it can be tuned to the precise frequency desired ; with a small hole, if the chamber is ¼, 1 or 1½ of a wave-length, it will admit energy readily ; if ½, ¾ or 1¼ wave-lengths, it will repel energy, that is, be anti-resonant. Since the wave pattern in a resonator is fixed, it is possible to locate a detector at precisely he right spot in the pattern in order to obtain maximum response.

Somewhere along the frequency scale in the neighbourhood of a billion cycles per second—wave-length about one foot—micro-wave technique undergoes a marked change. Methods using the conventional go-and-return-conductor type of circuit give way to the somewhat simpler hollow pipe, or wave guide, circuit. These newer methods seem to be at their best in the centimetre wave-length range. At the longer wave-lengths, the component parts become nconveniently large. For shorter waves, it would appear that ability to manufacture small parts would become an important limitation. What the technique will be beyond this point is a matter for the future.

THE INSECTS OF GUAM

By DR. A. D. IMMS, F.R.S.

A KNOWLEDGE of the insect fauna of small but important islands is very desirable before such fauna is inevitably changed by the operations of man and species have become extinct. In certain cases this must have happened even before some animals were discovered, as in Hawaii, for example.

The island of Guam is very isolated in the waters of the Pacific Ocean and measures nearly 30 miles long and 4–8 miles wide. A rainfall of about 90 inches per annum is usual and mostly during July–November. The northern half of the island is an elevated limestone plateau originally covered with tropical jungle, of which much still remains. Areas with sufficient soil are occupied by gardens and small farms, and there are a few small settlements. The southern half of the island includes a low volcanic range of mountains near the western shore, the highest peak being 1,334 ft. Streams on the eastern slope are the larger, and at the mouths of the valleys are located coastal villages. Much of the farming is carried on in the valleys, especially rice culture. On the plateau region are some cattle ranches. Rice is the only irrigated crop : not enough is grown to supply all needs and in 1936 importations were made from Japan. Other crops are corn, copra and many kinds of fruits and vegetables.

The foregoing remarks are mainly taken from an account entitled "Insects of Guam I.", which forms Bulletin 172 of the Bernice P. Bishop Museum, Honolulu (1942). This account is made up of some twenty-seven articles by specialists on different groups of insects, and presents the results of studies made on material collected during an entomological survey of the island in 1936. The survey was conducted under the auspices of the Hawaiian Sugar Planters' Association for the purpose of studying insects of economic importance in Guam. This island is the most important station between the Philippines and Honolulu on the route of Pan-Pacific Airways. Unknown insects were already being found in planes arriving in the Hawaiian Islands, and notwithstanding precautions by fumigation of aircraft, an occasional insect was found which had not fully succumbed. There is concern lest unknown pests, injurious to sugar cane or other Hawaiian crops, might gain an entry and become established in the archipelago. It is noteworthy in this connexion that about fifty species of pests of cultivated plants are known in Guam which are not known in Hawaii. The Sugar Planters' Association has always adopted a broad-minded and scientific policy, and it recognizes that among these insects of Guam are no doubt many that would become pests should they reach the Hawaiian Islands and become established therein. Furthermore, the insect fauna of the island is very inadequately known.

Among the various groups of insects dealt with in this bulletin no discrimination is made of those of economic importance—all come in for discussion and description of their species where necessary. It is noted that eleven species of dragonflies and twenty-two species of Thysanoptera but only three species of Aphididæ and a single species of Aleurodidæ are recorded. Butterflies number fourteen species, which is in contrast to the whole Hawaiian Archipelago, which only supports ten species. The Guam butterflies are mostly immigrants, possibly some of recent arrival, as only three or four species had been previously recorded. The most notable are the 'Monarch' *Danaida plexippus* and *Hypolimnas bolina*, the latter being widely distributed in countries and islands in and bordering the Pacific Ocean. Moths are not included in this volume except the Sphingidæ, which number five species, including the cosmopolitan *Herse convolvuli*. Of the Coleoptera the Curculionidæ, with forty-nine species, head the list ; among them no fewer than thirty-three species and eight genera are described as being new. Among Hymenoptera twenty-nine species of ants and ten species of wasps are enumerated. Of the ants nine of the species have been already recorded from the Hawaiian Islands. Only a few Diptera are included in this volume : they comprise, among others, five species of mosquitoes, including the notorious *Aedes ægypti*. A second volume of the survey, dealing with other groups of insects, is promised at a later date when these studies have been completed.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Saturday, July 10

Institute of Physics (Industrial Radiology Group) (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2.30 p.m.—Open Discussion on Industrial Radiology.

Sunday, July 11

Association of Scientific Workers (at Birkbeck College, London, E.C.4), at 7 p.m.—Meeting to discuss British Science in the Allied War Effort and to exchange greetings with Soviet men of science meeting in Moscow. Speakers: Prof. J. D. Bernal, F.R.S., J. G. Crowther, Prof. S. A. Sarkisov, and Sir Alfred Webb-Johnson.*

Monday, July 12

Association of Austrian Engineers, Chemists and Scientific Workers in Great Britain (at the Institution of Structural Engineers, 11 Upper Belgrave Street, S.W.1.), at 7.15 p.m.—M. Frantisek Nemec, Minister of Industry and Commerce and of Economic Reconstruction to the Czechoslovak Government: "Economical and Technical Reconstruction in Central Europe".

Tuesday, July 13

Quekett Microscopical Club (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 7.30 p.m.—Dr. J. R. Baker: "The History of Microscopical Staining Technique".

Thursday, July 15

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Edward Mellanby, K.C.B., F.R.S.: "Nutrition in Relation to Bone-growth and the Nervous System" (Croonian Lecture).

Friday, July 16

Physical Society (at the Royal Institution, Albemarle Street, London, W.1), at 5 p.m.—Brigadier Basil F. J. Schonland, O.B.E., F.R.S.: "Thunderstorms and Their Electrical Effects" (Charles Chree Address).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer in Education and in the Training Department of University College, Cardiff, with special qualifications in science, preferably physics and chemistry—The Registrar (July 16).

Lecturer in Physics at the Polytechnic, Regent Street, London, W.1—The Director of Education at the Polytechnic, stamped addressed foolscap envelope for application form (July 19).

Lecturer in Ferrous Metallurgy at the Chesterfield Technical College—The Clerk to the Governors (July 23).

Assistant Secretary—The Secretary, Institution of Gas Engineers, 1 Grosvenor Place, London, S.W.1 (July 26).

The Johnston Chair of Biochemistry in the University of Liverpool—The Registrar (July 31).

Demonstrator in Anatomy (male or female) in the University of Sheffield—The Registrar (August 2).

Assistant Works Manager, Metal and Steel Factory (Government of India)—The Ministry of Labour and National Service, Central (Technical and Scientific) Register (Reference ON.F.607), Alexandra House, Kingsway, London, W.C.2.

Chief Metallurgist for ferrous and non-ferrous work at Metal and Steel Factory, Ishapore (Government of India)—The Ministry of Labour and National Service, Central (Technical and Scientific) Register (Reference ON.F.1002), Alexandra House, Kingsway, London, W.C.2.

Secretary of the Institution of Professional Civil Servants—The Honorary Secretary of the Institution, 17 Hans Place, London, S.W.1.

Lecturer in Physics and Pure and Applied Mathematics at the Neath Mining and Technical Institute, Glamorgan.—The Principal.

Teacher of Mathematics and Science in the Junior Technical School, North-East Essex Technical College and School of Art, Colchester—The Clerk to the Governors.

Lecturer in Horticulture at Bishop Otter College (Women Teachers' Training College) at the Old Palace, Bromley, Kent—The Principal.

THE ATLANTIC CHARTER AND ITS AGRICULTURAL IMPLICATIONS

WHEN the Atlantic Charter was announced, it was widely acclaimed as embodying the great ideals at which administrators all over the world should aim. There was indeed no novelty in the ideals themselves; they had been put forward many times before. The new feature was their acceptance by politicians as not only desirable but also practicable, and therefore to be incorporated in their political programmes. The first step was to call a conference of representatives of the Allied Nations to discuss appropriate action, and this was done by the United States Government. The conference met at Hot Springs, Virginia, during May 18–June 3, 1943; no less than forty-four countries participated. In order to keep the discussion within bounds and to ensure so far as possible a practical outcome, the Conference restricted itself to the consideration of "the goal of freedom from want in relation to food and agriculture", to quote its own words; "freedom from want," it stated, "means a secure, adequate, and suitable supply of food for every man". The results of the deliberations have recently been published as a White Paper.

The numerous technical points that arose are dealt with elsewhere (p. 68); it is proposed here to discuss some of the broader issues. The basic recommendation sounds self-evident but actually involves the most far-reaching consequences; it was that "the Governments and authorities represented should declare to their own people and to one another their intention to secure more and better food for the people", and this was embodied in a resolution which epitomizes the whole of the deliberations of the Conference; each Government bound itself to provide for its own people the highest standard of nutrition which it could achieve, and each undertook to collaborate with the others "so that levels of food consumption may become more equitable, not only among the different sections of the population in a given country but among the several nations of the world as well". It was recognized that food policy and agricultural policy are inseparably intertwined, and during the discussions it became evident that the types of food most generally required to improve the peoples' diets and health are in many cases those produced by methods of farming best calculated to maintain the productivity of the soil and to increase and make more stable the returns to agricultural producers. Better nutrition, in short, means better farming. Seeing that more than two thirds of the human population are producers of food, any improvement in their position must be for the advantage of mankind as a whole.

Next it was shown that there is a close interdependence between the level of employment in the different countries and the standards of nutrition. But the level of employment in turn depends on the character and extent of the industrial development, the management of currencies, the direction of national and international investment, and the policy adopted towards foreign trade. While it could not investigate the methods needed to promote expansion of economic activity, the Conference declared that freedom from want could not be fully attained without this expansion, and recommended that the various Governments and authorities should take action, individually and collectively, to achieve it.

So large a proportion of the human race has hitherto been underfed that higher nutrition for all people even in Europe would necessitate a greatly increased output of food, and if Africa and Asia were included an enormous increase would be required. But the Conference remained undaunted and was convinced that the necessary supplies could be produced. Machinery, however, would have to be set up for dealing with the gluts of food periodically accumulating in bounteous seasons, which have hitherto proved very detrimental to farmers and consumers alike, and of advantage only to certain financial operators. To deal with this it was proposed that 'buffer stocks' should be set up to absorb the excesses of good years and deal them out to places where more food is needed. Finally, it was agreed that matters should not be allowed to rest with the mere publication of these resolutions; a permanent organization should be set up to help in carrying them out, and the task of establishing this body and of attaining the other objectives set forth in the resolutions was assigned to an interim commission composed of one representative of each country, which should meet not later than July 15, 1943. The United States Government accepted the responsibility for calling together this body.

If these proposals are acted upon by the participating nations, a profound change will be produced not only in agriculture but also in world politics. Hitherto three different policies have been adopted in regard to food production. During the *laisser-faire* period of the nineteenth century, the purpose was to give the greatest amount of profit to the individual, but to leave things entirely in his hands, the Government neither deliberately helping nor deliberately hindering him. It was expected that each country would produce the commodities it could most easily and cheaply supply, and the different countries would then exchange their surpluses. This led to specialization, which had many advantages; but in the end the resulting 'mono-culture', as it became termed, proved fatal to the soil; it led to the 'dust bowl' of western North America, and to soil deterioration and soil erosion in many other countries; according to the *laisser-faire* policy, the present owner of the land was entitled to ruin it if it suited him, and no responsibility to the future need be entertained. Quite apart from the bad ethics, there was much bad economics in the system, for when the market requirements changed or a cheaper producer appeared, the cultivators might be ruined before they could find new products and effect the necessary changes in their agriculture, which is always a slow business. This policy has therefore been given up.

Another policy widely adopted was self-sufficiency. Each country should produce all the necessary food that it can, and it should learn to go without those products that could be obtained only from oversea This policy was closely linked up with preparatio for war, either aggressive or defensive. A natio dependent on imports of food, it was argued, woul be in a weak position when war broke out, an indeed the issue might be decided by simply cuttin off its imports. This policy was enthusiasticall adopted by Germany and Italy before the War, an more or less reluctantly by some of the adjacen countries, which felt they had no option but prepare for contingencies.

The third policy is that of optimum nutritio which the Conference adopted. Strictly speaking, has never been tried in all its fullness, but son countries came near to it, notably the United Kin dom, the Dominions, the United States, Denmar Holland, Belgium and Switzerland. For these, con paratively small changes in the type of agricultu would be needed if the high nutrition policy we generally adopted in practice.

The Conference decisions have come as no surpri to agriculturists. A high nutrition policy was pr posed at Geneva in 1934 by Bruce and McDougal Australia, and its implications worked out by O and others; an unofficial group of agriculturis organized by Lord Astor examined its agricultur consequences for Great Britain. It was considere and to a greater or less extent embodied, in each the proposals for the reorganization of British agr culture put forward by the various important r sponsible bodies and by many smaller less-know groups of people. The high nutrition policy nece sitates some degree of planning in agricultur production and this means some degree of control all the responsible bodies are prepared to accept thi It means also something in the nature of a nation contract between farmers on one side and consume on the other, which, of course, implies agreed pric having relation to the costs of production, and pr visions to ensure delivery of the commodities in th agreed quantities and of approved quality; in othe words, power to enforce efficient farming. This als is commonly accepted. The differences between th various sets of proposals are in detail only.

The Royal Agricultural Society, the most widel representative body of all, recommends that a no political statutory body, a Food Commission some what on the lines of the Forestry Commission, shoul be set up in Great Britain to ensure adequate foo production, the maintenance of soil fertility, and price-level sufficient to yield a reasonable profit o average land after payment of adequate wages. Th Government should decide the proportion of th different foodstuffs to be produced at home and i should maintain the price-level by imposing impo duties, not by direct subsidies. Steps would need t be taken for raising the efficiency of farming; ther must be better production, better marketing an distribution, more research, more effort to apply th results of science, and more, and more suitabl education. The National Farmers Union, whic includes a large proportion of the farmers of Grea Britain, proposes the setting up of a Foo Ministry which would regulate supplies and price but as a safety measure there should be maintained in England and Wales a minimum of 11 million acres of tillage land (that is, arable land, *less leys*) including 2¼ million acres of wheat, 600,000 acres of potatoes, 400,000 acres of sugar beet and 800,000 acres of fruit and vegetables; for the ten years prior to the War the actual average figures were: tillage land, 7·1 million acres; wheat, 1·6 million; potatoes, 475,000; sugar beet, 318,000. Price control of wheat and meat should be effected by organizing marketing and imports on the lines recommended by the Sydney Conference of 1938.

The proposals of the Conservative Party also necessitate price stability and satisfactory price-level, effected by controlling the imports of food by an Import Board and a levy subsidy, even in some cases a high tariff. Direct subsidies are to be avoided. Measures for increasing the population and improving the level of nutrition would be welcomed within limits, though a nutrition policy would not obviate the need for general price stability.

The recent memorandum issued by a "Group of Peers holding varying Political Creeds" boldly adopts the nutrition policy, and urges that in our dealings with other countries we should press them also to adopt it. Tariffs afford no solution to the price problem, nor do direct subsidies. They divide agricultural produce into two groups: commodities, the production of which is incidental to good husbandry, such as wheat (oats in Scotland), sugar beet, and meat; and those needed for high nutrition, such as milk, poultry products, fruit and vegetables. For the former it would be essential to set up import quotas at prices agreed beforehand. For wheat, as a safety measure, home production should be approximately the 1939 acreage plus 10 per cent; the price paid would be based on the average cost of efficient production, but the consumer would pay less because he would benefit by the lower price of imported wheat. Any gluts would be cleared by selling at specially low prices to nations below the poverty line. The other products would find a ready market if a nutrition policy were adopted by the nation; at present we do not produce nearly enough of them. For milk, eggs, fruit and vegetables, an increase of 60–70 per cent on pre-war figures would be needed, as well as an additional 25 per cent output of meat.

There is much evidence also that the people of the occupied countries of Europe are ready to accept a high nutrition policy. Certainly they have had a bitter enough experience of the self-sufficiency policy. It was carried out more thoroughly and systematically in Germany than anywhere else, and yet there it gave its people much less of the delectable foods than we had in Great Britain; on the average, only one half our beef and our sugar, very little lamb, only about two thirds of our butter and eggs, and much less fruit. To make up for these deficiencies they had double our rations of potatoes. In other countries things were worse, and a high nutrition policy would be a welcome change. Admittedly it involves difficult economic and administrative problems, but it seems to offer the best hope for reconstruction and for permanent peace. It fully deserves a trial.

AFRICAN GEOMORPHOLOGY

South African Scenery

A Textbook of Geomorphology. By Dr. L. C. King. Pp. xxiv+340+144 plates. (Edinburgh and London: Oliver and Boyd, 1942.) 25*s*. net.

A YEAR ago, C. A. Cotton published a text-book of geomorphology in which the account was illustrated primarily from the topography of New Zealand. A similar volume by Dr. L. C. King, taking its examples from South Africa, has now become available. Whereas New Zealand provides unsurpassed examples of land forms developed in a humid climate, South African scenery has developed under conditions of limited rainfall, often approximating to desert. The new book thus covers a range of phenomena different in detail from those described by Cotton, and the two books are in many ways complementary.

The scope of "South African Scenery" is wider than one might expect. "South Africa" is conveniently taken as the part of the continent south of the equator, so that it is possible to include an account of the East African rift valleys, lakes and volcanoes, and thus extend the description of land forms beyond those available in South Africa proper.

The greater part of the book is devoted to description of the development of land forms by the various erosive agencies, and to their modification by earth movement and volcanic action. This is treated on stereotyped lines, but gains greatly in interest from the constant reference to excellent examples, mainly in southern Africa, and from the freshness of the examples chosen. The land forms are linked with the geological history and surface geology throughout, with a resulting great gain in understanding of the development of the scenery.

An account of the disastrous effect of ravine formation and resulting soil erosion, and of the methods of prevention, is of particular interest in view of the growing importance of the subject. The enactment of new legislation by the Government of Kenya has just been announced, for example.

King makes frequent reference to the effects of Pre-Karroo, Cretaceous and Tertiary periods of erosion, and their separation and identification is a feature which helps to make South Africa unique to geomorphologists. One is, however, inclined to feel that some account might also have been given of the dating of South African river terraces and climatic fluctuations by means of human cultures and the contained fauna, now that information of this kind is becoming available. For example, it would have been more illuminating to have stated that the Victoria Falls have retreated five miles up-stream since the Middle Pleistocene, rather than since man first appeared in the region, and a summary of the evidence bearing upon the date of Pleistocene earth movements would be a welcome addition.

One of the more interesting subjects on which King touches is the uplift of the southern and central parts of the African continent. In East Africa this uplift amounted to 3,000–5,000 ft. over vast areas, and there is evidence to show that it has taken place over a period covering most of Tertiary times. It was largely completed by the end of the Pliocene. The associated rifting movements, however, form a complicating factor and hinder full analysis. In South Africa the rifts are absent, but a comparable uplift has nevertheless taken place. Du Toit

(*S. African Geog. J.*, 16, 3 ; 1933) has given a detailed account of the history of this uplift, which has raised the "Great Miocene Peneplain" to 4,000–5,000 ft. in the High Veld, and King reproduces much of the most recent information on the subject.

When the Miocene peneplain was formed, the surface of South and East Africa must have been nearly at sea-level, and in isostatic equilibrium for a long period. In East Africa the uplifted peneplain is still in isostatic equilibrium, and fossiliferous Miocene beds remain to prove that the surface has not been lowered appreciably by erosion since the middle Tertiary. In South Africa, du Toit suggested that the uplift was due to "unloading under erosion", but King states that the Miocene peneplain is clearly identifiable in the High Veld, and there is in any event no obvious reason for the adjustment having been so greatly overdone. Thus four thousand feet of vertical uplift has affected a third of a continent, without any important folding or thickening of the crust. What changes in the subcrust have produced this remarkable effect ?

A general description of the Rift Valleys and the theories of their origin follows the detailed discussion of effects of the more common types of earth movement. Here King disposes of the rather surprising suggestion advanced a few years ago that the rift valleys owe their formation largely to erosion, and goes on to describe the conflicting tectonic theories of their origin. The 1938–40 eruptions of volcanoes of the western rift in the Belgian Congo are illustrated by an excellent series of photographs, which demonstrate vividly the surface features of recent lava flows.

The latter part of the book consists of a description of the topography of Southern Africa on a regional basis. This section deals first with Central and South-Central Africa, describing the geological history of each country in so far as it affects the physical features, and then goes on to describe the surface features of South Africa *sensu stricto* by natural regions. A considerable proportion of the information in this section is derived from work of the last twenty years, and the description is particularly valuable. This part of the book might perhaps have been improved by extension of the natural region treatment to the whole area instead of using political boundaries for Central Africa, which involves division of the description of the western Rift Valley, for example, between Uganda and the Belgian Congo.

The volume has the disadvantage common among books of this kind in that the only references given are suggestions for further study, and no mention is made of the sources of information or authors of hypotheses. These would be especially welcome in view of the recent character of much of the work on which description is based. One regrets, for example, the omission of any reference to Wayland when the results of his work in Uganda are described at some length in the text. Similarly, although Bailey Willis's monograph on East African geomorphology is quoted in the short bibliography, no reference is given to show where his work is reproduced.

"South African Scenery" is excellently produced and written. The richness of illustration may be indicated by the statement that the book has 144 half-tone plates to 340 pages of text. No one will read this volume without realizing that southern Africa is not merely a country of monotonous peneplain but also has areas of extreme grandeur. The book is a really worth-while possession.

P. E. KENT.

POPULATION AND EMIGRATION

The Political Economy of Population

By Prof. Radhakamal Mukerjee. (Lucknow University Studies, Faculty of Arts.) Pp. xiv+467 (London, Bombay, New York and Toronto : Longmans, Green and Co., Ltd., n.d.) 7*s.* 6*d.*

THE author is the personification of energy and versatility as he pours out book after book devoted to the setting forth of the facts, and inferences, of human ecology. For us, in Europe, he has the added value that he knows a great deal about us and writes in our language, a rather American English, while at the same time speaking from the point of view of a member of the huge concentration of half mankind on the relatively small space of the Monsoon Lands. Mukerjee continually reiterates that political economy, biology, genetics, politics and sociology all fall short because they look at selected elements and neglect others which are vital for the understanding of a composite social process that, in his view, may claim success if it maintains a balance of activities and population that can go on indefinitely. The solution of the population problem in Europe lies neither in the sacrifice of children to the pursuit of a highly artificial standard nor in the sacrifice of personal values to the prestige of the State ; he seeks, rather, a balance. Perhaps he is not explicit enough concerning the mentality apt to spread when decline of population is imminent ; we Europeans know its difficulties only too well from the case of France, 1923–1940.

This book touches briefly a great many, too many, topics, and thereby illustrates our difficulty in scientific study if we try to diminish the undoubted evils of highly selective specialization, but it has many thoughts worth pondering. The author wonders whether high net reproductive rates may not be associated with food rich in vitamin E ; this is, perhaps, one factor but, so far, it would seem wise to moderate such claims. Like other writers, Mukerjee emphasizes the change from the mid-nineteenth century when the vast spaces of western North America seemed to offer limitless opportunities, to the present day when the misuse of some of those opportunities has brought such disastrous results, and he is concerned to show that the more thoughtful members of our populations must be encouraged to accept the responsibilities of parenthood.

The movement of people from the crowded monsoonal lands of Asia and its diminution since the economic catastrophe of 1929–32, with a partial revival for a short time in 1934–35, leads him to discuss the man-made barriers to immigration into the empty lands, and the relatively low birth-rates among important sections of the populations of North America, Australia and New Zealand. He thinks Asiatic peoples might spread a rice-economy in Central America, northern South America, the Guinea coasts of Africa, the south of the Congo basin and elsewhere, and that the East Indies could gain from large-scale immigration. Probably the peoples of European origin who have now spread beyond Europe and North America amount to 10 per cent of Europe's population. Asiatics outside Asia are not only a far smaller proportion of their home populations but also are actually much less than half the number of the Europeans who have spread beyond their two continents, and he pleads for "The Open Door". It is a serious plea and not an easy one either to refute or to accept.

H. J. FLEURE.

AMERICAN ARMY NATURALISTS

Ornithologists of the United States Army Medical Corps

Thirty-six Biographies. By Colonel Edgar Erskine Hume. (Publications of the Institute of the History of Medicine, the Johns Hopkins University, First Series: Monographs, Vol. 1.) Pp. xxv+583. (Baltimore, Md.: The Johns Hopkins Press, 1942.) 5 dollars.

IN this volume Colonel Hume has collected a great deal of interesting biographical information on thirty-six members of the United States Army Medical Corps, who at one time or another were connected with the study of birds. A few of the names are well known outside the United States, such as Charles Bendire, author of "Life Histories of American Birds", Robert Shufeldt, a great student of bird anatomy and contributor to Newton's "Dictionary of Birds", and Eliot Coues, a prolific writer and best known by his outstanding book "Key to North American Birds". The majority, however, are only known to students of works on North American birds, since much of their work was done during the Pacific railroad surveys, and different boundary commissions.

It was, indeed, fortunate that the Government appointed Prof. Spencer Baird, assistant-secretary to the Smithsonian Institution, as naturalist to the railroad survey, since he guided and encouraged the young medical officers who were attached to the different working parties in collecting and observing birds.

One ornithologist claimed by the Army appears as a surgeon in the Navy. This was J. H. Kidder, who began his career in the Army and later transferred to the Navy. In 1874 he accompanied the Transit of Venus expedition to Kerguelen, where he made extensive collections in all branches of zoology and botany. The results were published by the Government under the title of the "Natural History of Kerguelen". By the members of his profession Kidder is best remembered as the founder of the Naval Museums of Hygiene at Washington. It is difficult to understand how John Xanthus became assistant surgeon, and there is much mystery and romance about his career. It appears he was of a good Hungarian family, went to the United States about 1848 or thereabouts, joined the Army as a dresser, and became an assistant surgeon although he had no medical degree. On leaving the Army he served as consul for a short time in Mexico, and then returned to his native land. He does not seem to have been very reliable, but nevertheless Prof. Baird considered him an accomplished collector.

Apart from Shufeldt and Coues, the outstanding figure among the thirty-six names is Colonel E. A. Mearns, who died in 1916. It is computed that there are in the National Museum some 37,000 specimens of vertebrates collected by Mearns, and his contributions to the herbarium are greater than any other individual. Mearns, however, was no mere collector; he kept copious notes and, when time allowed, worked out his collections himself. His first important post was medical officer and naturalist to the Mexican Boundary Commission, and he also served in the Philippines for several years. When President Theodore Roosevelt went on his hunting trip in Africa, he applied to the National Museum for a collector, and Mearns was recommended as the best field naturalist and collector in the United States. The appointment gave every satisfaction, and many notes on game animals and birds in "African Game Trails" are from the note-books of Mearns.

THE VERTEBRATE RETINA

Vertebrate Photoreceptors

By Prof. Samuel R. Detwiler. (Experimental Biology Monographs.) Pp. viii+184. (New York: The Macmillan Company, 1943.) 4 dollars.

THERE is a fairly widespread belief, at least in Great Britain, that not only the brain but also the eye reaches its highest stage of evolution in man. Comparison of the human eye, with its capacity for colour vision, binocular vision and the resolution of fine detail, with those of the restricted group of mammals usually studied, does lend support to such a view, but if one turns aside to consider the eyes of the non-mammalian vertebrates it immediately becomes untenable. Granit's recent work on the differential sensitivity of the retinas of a selection of the lower vertebrates to different parts of the spectrum has shaken our belief that the perception of hue is the prerogative of the primates, some insects and, possibly, the birds. It seems most likely that an animal, such as the owl, with frontally placed eyes, must have binocular vision in spite of the complete decussation of its optic nerves, and no one who has watched a kestrel hover and then stoop on its prey can doubt that its visual acuity must be far higher than our own. Walls' detailed studies of the eyes of many vertebrates have led him to the conclusion that the eye of any given animal has usually reached that stage of development, or sometimes of regression, best suited to serve the needs of its mode of life, and the human eye does not appear to differ from any other in this respect. Man's superiority is not so much due to his better visual apparatus, as Elliot Smith suggested, as to his greater ability to make use of the information supplied by his eyes.

So far there has been but little interest in the eyes of non-mammalian vertebrates in Great Britain, and it is to be hoped that the appearance of Detwiler's new book on vertebrate visual cells, so soon after that of Walls on the vertebrate eye in general, will help to stimulate interest in a fascinating and much neglected subject.

In this book Detwiler is concerned with the structure, development and physiology of the retina, and particularly of its rods and cones. Much of the subject-matter is based on his own work but, on the whole, he is unusually generous in his appreciation of the contributions, both of observation and theory, of other workers. The exceptionally balanced and objective attitude adopted throughout the greater part of the book does, perhaps, result in a certain lack of liveliness, and it is possible that readers who are less concerned with a rather narrowly specialized subject than the reviewer may find it somewhat difficult to maintain their interest. The chapter on the evolutionary significance of the fovea, the only one in which the author comes out wholeheartedly on one side in a controversy (in this case against the theory propounded by Elliot Smith), is certainly the most entertaining. Sometimes, also, one cannot help feeling that Detwiler has gone too far in his kindly attitude towards some ideas which might be allowed to disappear into a well-deserved obscurity. It is surely no longer necessary, for example, to discuss the possibility that the rods and cones are derived from the cilia lining the optic vesicle, since these are now known to disappear long before there is any sign of the developing visual cells.

The chapter on retinal photopigments is unexpectedly weak. Except for the discussion of Kolmer's droplets and their possible constitution, this chapter is based entirely on the work of Hecht and Wald, and the very important and fundamental work of Lythgoe and his colleagues on visual purple and the products of its bleaching is not so much as mentioned. Even the description of Wald's results is confused, although perhaps Detwiler should not bear the whole blame for this, since there are several discrepancies between Wald's earlier and his later papers which have never been properly cleared up. Attention must also be directed to the statement on p. 122 that "[Wald] showed—that the spectrum of pure rhodopsin (visual purple) corresponds in form and position with the spectral sensitivity of human rod vision computed at the retinal surface". Since no other name is mentioned in this connexion the implication is that Wald was the first to demonstrate this correspondence, yet the figure used on p. 121 to illustrate the point was actually published by Trendelenberg so long ago as 1904.

For the rest, the book is excellent and thoroughly reliable. There is a very clear and concise account of Polyak's investigations of the nervous structure of the retina, which is especially welcome since this worker's results are of the most fundamental importance to our understanding of the nervous physiology of vision and are by no means so widely known as they should be. The illustrations consist largely of photomicrographs, many of them made from the author's own preparations and most of them very good.

KATHARINE TANSLEY.

LANGSTROTH, THE APIARIST

The Life of Langstroth

By Florence Naile. Edited, with a Foreword and an Introduction, by Prof. Everett Franklin Phillips. Pp. 215. (Ithaca, N.Y.: Cornell University Press; London: Oxford University Press, 1942.) 15*s*. 6*d*. net.

BEEKEEPERS have waited a long time for a life of Langstroth, but Miss Naile has now produced a pleasantly written and well-arranged volume, attractively got up, which contains all that has been known about Langstroth and a good deal (especially about his ancestry and early years) which will be new to her readers. Prof. E. F. Phillips, professor of apiculture at Cornell University, has supplied the foreword and introduction, and the volume may be regarded as the official American 'life' of Langstroth.

The book has, however, been published during a great war and in consequence has suffered markedly from undue compression. We hope that if a second edition appears it will include more about Langstroth the man, as distinguished from the beekeeper. We should like to know more about him as a preacher, to see a photograph of him in the midst of his family and to know more about his wife and his children; at present the volume seems lacking in human feeling.

In other respects, too, lack of space seems to have made itself felt. When the controversy about Langstroth's patent was dealt with, the position as regards frames should have been explained, and the omission is the less excusable as Colonel Walker discussed the matter fully in a series of articles in the *British Bee Journal* of June 1, 1922, and reprinted in "Beekeeping New and Old", vol. 1, p. 126. Munn, too, and his hive should have been mentioned, as he was a friend of Dr. Bevan, that medical man whose portrait reminds one irresistibly of Pickwick, and whose "Honey Bee" was the best book about bees in its day (in the English language) and seems to have been the source from which Langstroth obtained his first ideas about systematic beekeeping.

Another point worth noting is that a frame is surrounded by six bee spaces; Langstroth first discovered the one above the frame and, later on, those at its base and ends; those on each side had been hinted at by Thomas Wildman (1768 Edn., p. 53).

On November 29, 1851, the *Gardeners' Chronicle* remarked of the American hives exhibited at the 1851 Exhibition, "North America is as fertile in rubbish as the mother country itself", and we think it is correct to say that Langstroth's service to his own generation was the simplification and partial standardization of the design of hives, which, by making them boxes for containing movable frames, enabled the beekeepers of that day to deal with the larger bee moth which, at that time, was reducing American apiaries to ruin. Later generations are inclined to regard him as the man who made extractors, comb foundation, swarm control and other essentials of modern beekeeping possible.

Langstroth's statement about "a small book, the author of which seemed to doubt the existence of such a thing as a queen bee" (p. 64) was quite correct but scarcely did justice to the first bee book he possessed. Jerome V. C. Smith, the author of "An Essay on the Practicability of Cultivating the Honey Bee in Maritime Towns and Cities", was a doctor of medicine who afterwards became mayor of Boston. The book is not a systematic treatise on the art of beekeeping, but it is extraordinarily suggestive and stimulating, and a comparison with the works of contemporary American authors will, we think, convince the reader that Langstroth was remarkably fortunate in his first bee book.

In conclusion, we venture to hope that Miss Naile will continue her study of Langstroth's life and work. We should like to see two more books on the subject from her. The list of Langstroth's library requires a good deal more emendation, and a booklet which dealt with it could be made very interesting. A study of "Langstroth on the Honey Bee" is also required. Americans should be helped to see how Langstroth showed capacity to discriminate between what was correct and incorrect in previous writers and whence he obtained his knowledge and, more especially, attention should be directed to any statements which appear to be original. The illustrations, too, should be examined. (The references are to the 1879 edition of Langstroth's book.) The picture of bees surrounding the queen which appears on the title-page was suggested by one which appeared on p. 48 of Dionysius Lardner (Museum of Science and Art, vol. 10, 1856); Fig. 65 on Plate XIII is Fig. 1 on Plate II of Dunbar's work and Fig. 55 is Dunbar's Plate IV reversed (The Naturalist's Library, vol. 6, Edinburgh, 1840); Fig. 51 on Plate XVI is Fig. V on Tab. XVII of Swammerdam (edition of 1758), and other examples would, no doubt, reward careful study.

H. M. FRASER.

he Carnivorous Plants

By Dr. Francis Ernest Lloyd. (A New Series of Plant Science Books, Vol. 9.) Pp. xvi+352 (38 plates). (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1942.) 6 dollars.

THIS book is by far the most complete survey of the literature in a special, and naturally delimited, field; but it is also a contribution to knowledge in this field embodying many years of intensive work by a vigorous and original worker. Prof. Lloyd's own interest in carnivorous plants began with his studies of Utricularia, and in this monograph the descriptions of the organization and functioning of the many species in this genus and of the allied structures in the little-known genera Polypompholyx and Biovularia occupy a large proportion of the text. Prof. Lloyd's own contributions on the bladder of Utricularia extended considerably our knowledge of its structure and method of working, particularly as to the presence of the second valve membrane at the mouth, the velum, and its significance in facilitating the water-tight closure of the door necessary for the setting of the trap. When he extended his survey to cover other types of carnivorous flowering plants, besides making by far the most complete survey of the literature yet available, in every possible case he has examined material, living when possible, and in many cases as a result new facts are supplied as to development and structure, and he is able, from his first-hand knowledge of the plants under consideration, to give a critical and well-balanced survey of the work of earlier investigators.

Besides a number of text-figures, thirty-eight plates are included. These reproduce numerous original drawings and photographs. The drawings supply details of structure and development; the photographs usually illustrate habitat and have in many cases suffered in reproduction, in particular by the compression into a very crowded page.

In addition, the volume contains an interesting chapter reviewing the meagre facts available about some filamentous fungi which have either used the characteristics of their growth habit to weave hyphal snares for minute eelworms, or through the mucilaginous nature of their wall or contents immobilize and afterwards destroy various animalculæ.

Guide to the Stars

By Dr. Hector Macpherson. Pp. 137+10 plates. (Edinburgh and London: Thomas Nelson and Sons, Ltd., 1943.) 6s. net.

DR. MACPHERSON'S work has been produced primarily for the amateur astronomer, and its simple and lucid style renders it a very suitable book to place in the hands of the beginner. A brief outline of the universe, including the solar system, the galaxy and external galaxies, provides a useful introduction to the main portion of the work—a description of the constellations and their principal stars which are visible during the different seasons of the year. A number of star maps and also six plates at the end, containing eighteen constellations and stars down to the fifth magnitude, will prove very helpful to those who are anxious to learn the names of the stars. Chapter 9 is devoted to a description of the movements of the bodies in the solar system and contains a number of hints on the observations of the sun, moon and planets. A short account of eclipses, transits, occultations, the zodiacal light and the aurora borealis is given in the last chapter. The novice will find this small work an excellent introduction to the study of astronomy. There are a few slips of minor importance, of which the following may be noticed:

On p. 40 it is stated that the Great Nebula in Andromeda is the nearest of the external galaxies, but Messier 33 is a little nearer. P. 80, line 7 from top. This should read, "A line drawn from Zeta to Eta Ursae Majoris. . . ." P. 123. It is more correct to say that the maximum duration of a solar eclipse is about 7½ minutes, not 7 minutes. In the next paragraph, 111 days should read 11 days. M. D.

The Pocket Planisphere

By Francis Chichester. Pp. 4. (London: George Allen and Unwin, Ltd., 1943.) 2*s*. 6*d*. net.

THIS planisphere measures 5½ in. by 5 in. and can be carried in the pocket without the slightest inconvenience. It shows how the stars appear for each month on any selected day or hour to an observer in lat. 50° N. and also in lat. 35° S. On the rotating disk each month is divided into four portions, the first division being on the first of the month; and seven-day intervals are adopted in all cases except at the end of the months, when the arrangement necessitates intervals of nine or ten days. It is very easy interpolating and setting the planisphere for the selected day and also for the time of the night, intervals of one hour being used. As the space between successive hours is six-tenths of an inch, sufficient accuracy for fractions of an hour can be obtained. The names of the important navigation stars are in capitals and numbers are attached to other stars which the navigator may wish to use, a key to these numbers being printed on the back of the mask which covers the star disk. Directions for using the planisphere are supplied; it will prove a very useful equipment for the air navigator.

M. D.

Brompton Hospital Reports

A Collection of Papers recently published from the Hospital. Vol. 11, 1942. Pp. vi+136. (London: Brompton Hospital, 1943.) 5*s*. net.

VOL. 11 of the Brompton Hospital Reports contains fourteen recent articles published in the medical press by members of the hospital staff.

A. F. Foster-Carter contributes a well-illustrated report on "The Anatomy of the Bronchial Tree". "The Care of the Dying", by Clifford Hoyle, contains a great deal of information on points ignored by the standard works, and deserves a wider distribution than it is likely to receive in this specialized publication.

Physical Chemistry for Students of Biochemistry and Medicine

By Prof. Edward Staunton West. Pp. xiv+368. (New York: The Macmillan Company, 1942.) 28*s*. net.

THIS book is noteworthy for an excellent survey of recent developments in knowledge of atomic and molecular structure. The scope is wider than is suggested by the title, and it goes far beyond the requirements of the average medical student. It can be recommended as a book of reference for workers in biology and physiology.

SCIENCE IN CHUNGKING

By DR. JOSEPH NEEDHAM, F.R.S.

British Council Cultural Scientific Mission in China

THE present article is a continuation of the two recent contributions describing scientific work now going on in Yunnan province (south-west China). It will be followed by contributions on West Szechuan, on Kweichow and Kuangtung provinces (south-east China), and on the far north-west. It is hoped that by this means the mutual isolation of Chinese, British and American scientific workers may be mitigated.

Strictly speaking, Chungking itself is not a scientific centre any more than Westminster. The city, situated in a splendid position on a series of hills between the two great rivers where the Djialing joins the Yangtse, maintains its pride, and temporary houses have sprouted like bamboo-shoots all over the much-bombed areas. It has so often been described that a detailed account here is unnecessary, but the innumerable air-raid shelters blasted in the rock of the hillsides must be mentioned with praise. Life in the city is not so uncomfortable as is sometimes pictured, and always made agreeable by the unfailing good humour and spontaneous charm of the Chinese people themselves.

Among the Governmental organizations concerned with science, the National Resources Commission, presided over by the Economic Minister (himself a geologist), Dr. Wong Wen-hao, assisted by the able Mr. Chien Chang-chao, employs 165,000 workers up and down the country, and 12,000 administrative and technical personnel. Of the latter, more than 80 per cent are less than thirty-five years of age, including about 5,000 university graduates and about 400 technical and scientific experts who have spent many years in the West. The National Resources Commission is opening up natural resources everywhere in Free China, and its functions are to develop, operate and control basic industries, important mining enterprises, important electrical power enterprises, and also to administer other industrial enterprises as assigned by the Government. Like the Department of Scientific and Industrial Research in Britain, it subsidizes research in many universities, as well as research institutes. Then the National Health Administration, situated in a suburb, Bridgetown (place-names are purposely translated and garbled for security reasons), under Dr. Chin Bao-Shan, carries out the same functions as our Ministry of Health, and controls a National Central Medical Research Institute, to which I shall refer later.

In order to visit the important scientific work going on in the neighbourhood of Chungking, it is necessary to go out into the country some two hours motor ride in different directions. At Sandy Hook, for example, some distance up one of the great rivers which meet at Chungking, is to be found the National Central University, formerly at Nanking, but now occupying a site within the campus of the Szechuanese Chungking University. Both these universities push on with the teaching of scientific subjects in the face of rapidly dwindling supplies of essential chemicals and apparatus. In the chemical laboratory of the National Central University work is proceeding, under Prof. Kao Chi-Yu, on the parachor and on the effect of acids, bases and salts on the optical rotation of organic compounds; besides studies on oil paints and lacquer for aeroplane finishing. In the plan physiology and pathology department, Dr. She Chih-I (secretary of the Chinese Natural Scienc Society, an organization somewhat resembling ou Association of Scientific Workers) studies the viru diseases of Chinese crop plants and the peculia water requirements of rice varieties. In the biologic department, Prof. Ouyang Chu pursues the studie on brain histology which he began with Oscar Vog in Germany in former days, much handicapped b the damage which his microtomes suffered during th journey from Nanking. The physicists are als active. Dr. Sze Se-Yuan invents new cuprous oxid rectifiers, and means of making storage batterie locally, while also studying the production of per manent magnets with tungsten steel. Good work i proceeding, too, on the ultra-violet spectrum of th carbon monoxide molecule excited by bombardmen with electrons (Messrs. Chao Kuang-Tseng and Yan Chun-Chung). Nor is mathematical physics neglected Dr. Chang Tsung-Sui (formerly a pupil of Sir Ralp Fowler) is actively working on the theory of th meson, and papers by him have very recently bee communicated to Great Britain through the Britis Scientific Mission in China.

Of the other institutions at Sandy Hook, Chungking University specializes in chemical engineering, in which subject Dr. Peng Shou-Ling (formerly with Sir Alfred Egerton at the Imperial College of Science and Technology, London) takes a prominent place. There is also the National Central Technical College, a Government institution for the training of working mechanical engineers, under Wei Yuen-Kuang as director. Among the laboratories of this College is one for hydraulic engineering and irrigation, reminiscent of what the friends of the Cambridge Geography School are accustomed to refer to irreverently as the 'mud-pie department'. But nothing could be more important for China, and this laboratory is suitably situated in Szechuan, the legendary home of the Great Yü, China's earliest irrigation engineer, who "mastered the waters" at the dawn of history, and worked so hard that "in ten years he passed the door of his house three times yet did not enter in". Finally, the famous Nankai Institute of Economics is also situated at Sandy Hook.

Undoubtedly the greatest scientific centre is a small town, Windbox Gorge, lying on another of the great rivers. Here there are no fewer than eighteen scientific and educational institutions, most of them of great importance.

To begin with, there are two Institutes of Academia Sinica, the Institute of Biology and the Institute of Meteorology. The former, under the leadership of Dr. Wang Chia-Chi, is extraordinarily active, with some twenty scientific workers fully occupied. Dr. Wang himself is a well-known protozoologist, and besides being head of the Institute, he directs the protozoology department. The head of the department of vertebrate systematics is Dr. Wu Hsien-Wen; they are concerned especially with the taxonomy of the fishes, but also study fish ecology and physiology. Thus Chang Hsiao-Wei is studying interesting adaptations to life in mountain torrents (for example, the 'stone-climbing fish'), and Liu Chien-Kang the chloride-secreting cells in the gills of the paradise fish. Dr. Chen Shih-Hsien heads the entomology department; here work is proceeding on insect systematics, physiology (respiration, excretion, stridulation, etc.) and on the control of mosquito arvæ by fishes and the insect-catching plant Utricu-ria (Miss Tan Chuan-Chieh). Dr. Rjao Chin-Chih, he algologist, heads the department of botany, which deals largely with the systematics of the higher lants, notably the Umbelliferæ. A visitor, admiring the situation of the Institute high above the great iver, and viewing the work going on in it, feels that t has the true research atmosphere of the world's est laboratories.

The Institute of Meteorology is rather a charming contrast to that of Biology. It stands on a high hill-top far from the river, looking out over terraced rice-fields on all the slopes, and it needs much fewer workers. Under Dr. Lü Chung (director) and Chen Tze-Cheng, however, it is extremely efficient in massing observations by regular balloon ascents, tc., and has an excellent library.

No less important than these institutes, and on a much larger scale, is the Chinese National Geological Survey. Its present director is Dr. Li Chun-Yü, and is the successor of the internationally known V. K. Ting (who presided over the discovery of Peking Man) he has a distinguished position indeed. The Survey has three Divisions: that of Geology, which includes Palæontology, Mineralogy and Petrology, Geophysics and Seismography, and a Cænozoic Laboratory; that of Cartography; and that of Soil Science. The cartographical work (under Dr. Tseng Shih Ying) is very active, as also is the geophysical ide. Here Dr. Li Shan-Bang has shown the greatest ingenuity in constructing seismographs, a pendulum apparatus for the measurement of g, and accurate clocks, literally with pieces of scrap metal and whatever can be got in Free China's west. He is now held up for photographic registering paper, which the British Scientific Mission (among very many similar efforts) is trying to secure for him. The palæontologists are constantly engaged in working over the very large numbers of specimens which the field expeditions of the Survey are always bringing in. Dr. Yin Tsan-Hsun described, for example, immensely ich triassic finds newly brought from Kweichow province.

The library of the Geological Survey, situated some miles away from the main building, on a hilltop in most beautiful country, is one of the largest and best equipped which I have seen anywhere in Free China.

Two other Government organizations of the first mportance are to be found at Windbox Gorge. One s the National Bureau of Compilation and Trans-ation (under the Minister of Education, Dr. Chen Li-Fu), and the other is the National Institute of Industrial Research. The first of these, presided over by the eminent scholar, Dr. Chen Ko-Chung, conducts an enormous work of standardization. For scientific men, its most important function is the settling of Chinese versions of scientific terms, a matter of great difficulty in view of the wide divergence between Chinese language and thought and that of the West, where modern science originated. Of these standard dictionaries, fifteen have already appeared (dealing with astronomy, mathematics, physics, mineralogy, embryology, and the like), thirty-two more are nearly ready to print, and thirty-three more are still in card index form. The method adopted is interesting. First, all the technical terms are card-indexed, with their various Chinese versions, then a choice is made, and finally the whole is sent out in the form of mimeographed ledgers to all the experts in the subject in question, who indicate their agreement or disagreement. If deadlocks occur, conferences are called. The Bureau employs no fewer than 200 workers, of which 130 are university men, including some very distinguished scholars, ex-presidents of universities. This work by no means exhausts, however, the Bureau's activities. It is also responsible for examining the text-books used in elementary schools, middle schools, etc., for compiling new encyclopædias and dictionaries, for translation of books (both from and into Western languages), for issuing collected editions of the classics, and for producing booklets of popular education for the masses. It is safe to say that no other Government, save perhaps that of the Soviet Union, supports such a wide programme of purposive scholarship. In the view of the Chinese Government, moreover, the Bureau needs enlarging to at least double its present size. Among the books officially translated have been Stebbing's "Modern Introduction to Logic", de Broglie's "Theorie de la Quantification dans la nouvelle Mecanique", Haas's "Einführung in die theoretische Physik", Crowther's "Ions, Electrons, and Ionizing Radiations", Howell's "Textbook of Physiology", Truscott's "Treatise on Ore-Dressing", and Sidney and Beatrice Webb's "Soviet Communism: a New Civilisation".

Imposing also in size is the National Institute of Industrial Research, which has other centres besides the main one at Windbox Gorge. Under the directorship of Dr. Ku Yu-Chuan, it comprises sixteen laboratories (fermentation, oils and fats, pure chemicals, motor fuels, analytical, colloid, cellulose, ceramics, plastics, tanning, machine design, electrical textile, strength of materials, heat power, forest products, sugar, salt and alkali). We can only glance at a few of these. In the fermentation division, Dr. Chin Pei-Sung manages the Chinese National Collection of Type Cultures, and much work is being done on acetone, alcohol and butyl alcohol fermentations. The pure chemicals division (Dr. Li Erh-Kang) produced five tons last year of all kinds of pure acids, alkalis and salts, but this is, of course, not nearly enough for China's research and production needs. In the forest products division, a remarkable effort has been made to recover the wood tar from the innumerable peasant charcoal-kilns all over the province. These have been fitted with bamboo condensers, with the result that many tons of valuable acetone and acetic acid have been made available, thus laying the foundations of an important decentralized wood-tar industry. The peasant coke-ovens are now being dealt with in the same way, which will be even more important. The plastics division has done pioneer work in the use of soya-bean oil-press cake as a basis for plastics, and many articles are now in production from indigenous waste protein and carbohydrate sources. The motor fuel division (Dr. Ku Yu-Djen) is doing fine work in the cracking of vegetable oils and the purifying of the gasoline so obtained. This Institute corresponds, therefore, to all the activities of the Department of Scientific and Industrial Research and the Research Associations of Great Britain rolled into one, but following our former analogy, the National Physical Laboratory and the Fuel and other Research Stations must all be considered as having been transferred, with the loss of most of their equipment and no locally existing facilities, to the shores of Loch Assynt!

The last important Government organization at Windbox Gorge is the National Agricultural Research

Institute, with its divisions of potato husbandry (in which the well-known American geneticist, Dr. Theodore F. Dykstra, is now working with Chinese colleagues), rice husbandry, soil science and plant pathology. In the last-named division, Dr. Chu Feng-Mei has constructed a very ingenious apparatus, almost entirely out of bamboo, for the separation of the round nematode-infested grains of wheat from the healthy elongated ones. In this way the parasites are not perpetuated when the seed is sown.

We come now to three non-Governmental institutions in this same place. First, the Science Society of China has its biological laboratory there in a secluded valley. It is actively engaged, under the veteran Dr. Chien Tsung-Su, on plant and animal systematics. This was the society which for many years published the Chinese equivalent of NATURE and *Science*, *Ko Shioh*. The editor, Lu I-Tao, is now in Chungking, and hopes are entertained of its early revival. Then there is the All-China Institute of Geography, an organization supported by the Sino-British Board of Trustees. Prominent in this Institute are Ling Chao (a former pupil of Prof. P. M. Roxby at Liverpool), who is shortly leaving for an expedition in Sinkiang, and Yang Kai-I (from Edinburgh) is also going as secretary to the head of the scientific survey of that province. Finally, there is Futan University, relatively small in numbers of students, but with a high academic reputation. Its laboratories are mainly devoted to teaching, but in biology Dr. Hsieh Fen is working on the growth-rate of cyprinid fishes.

Something must now be said of the scientific work at another place, Singing Stone Valley, away in the sandstone mountains through which the river cuts its course. Here are located the National Central Hospital, the Shanghai Medical College, and the National Health Administration's Research Institute. This last corresponds closely to the British National Institute for Medical Research at Hampstead, but in subject is more akin to the Wellcome and Lister Institutes. Its buildings are new, with a particularly good auditorium, hidden away among the wooded rocky hills with the ricefields at their foot. Among the various divisions under the directorship of Dr. Chu Chang-Kan there are nutrition (Wang Cheng-Fa), sanitary chemistry and engineering, medical entomology (Ho Chi), parasitology (Yuan I-Chin), pharmacology and bacteriology (Mrs. Wang Rjo-Yü) Excellent work is going on in all these.

The Shanghai Medical College ranks very high as a medical school, with the famous Peking Union Medical College, Hsiang-Ya (Yale-in-China) Medical School, and the medical colleges at Chengtu. The able administration of the pharmacologist and expert in Chinese drugs, Dr. Chu Heng-Bi, stands for an exceptionally thorough grounding in the fundamental sciences underlying medicine, and for the provision of opportunities for scientific post-graduate work. In the present rural surroundings and with so little equipment, this last requirement can scarcely be adhered to, but the staff of chemists and physiologists is exceptionally good, and the student level as high as anything so far seen in China. Thus the biochemists, Chi Yueh-Feng and Rjen Bang-Chih, were pupils respectively of Profs. Treat B. Johnson (purines) and H. B. Lewis (sulphur metabolism) in the United States. Among the students here are many from the now exiled Hongkong University Medical School, and they have one of their professors, the obstetric surgeon, Gordon King, on the staff at Singing Stone Valley.

In conclusion, the persistence and success of Chinese institutions with so little help and facilities again clearly appears. British science and Government alike should spare no pains to send help to those who are, among the United Nations, in science's 'front line'.

NON-SOLAR PLANETS

By DR. A. HUNTER

THE possibility that other stars besides our sun may possess planetary systems is one that has been the subject of speculation for centuries. Double stars in plenty are known, of course, and the orbital separations of the components are often of planetary order. In these cases, if the system is fairly close to the sun, the component stars are easily separable in big telescopes, and their angular separation can be measured directly with a micrometer. But the immensity of cosmic distances ensures that all stellar companions which can be detected directly in this way are of stellar brightness. No planet reflecting as little light (relatively speaking) as, say, Jupiter could be seen or photographed from our solar system even if it accompanied our nearest stellar neighbour.

This is not to say, however, that we are precluded from discovering planetary systems attached to other stars. There is the possibility, for example, that the gravitational effect of a planet can be detected from careful observations of the position of its primary. From such observations bodies of stellar mass have already been discovered: perhaps the most famous case is that of the faint companion of Sirius, the existence of which was deduced from the perturbed motion of its primary more than ten years before it was detected telescopically. The difference between this case and that of perturbation by a planet is evidently one of degree and not of kind. Only recently, however, have observations of the requisite accuracy become available. These are the photographic observations made at many observatories all over the world for the purpose of determining stellar distances.

The principle employed is that of parallactic displacement, as used in ordinary surveying, the base-line used being the diameter of the earth's orbit. Careful measurements of the apparent direction of a star on one night and of its direction six months later are combined with our knowledge of the size of the earth's orbit to give the distance of the star. In practice, the observations are delicate, for even the closest star has a parallax of less than a second of arc. The work must be spread over many years if small observational errors are to be reduced to a minimum, and in order to eliminate systematic errors of period one year, which would obviously vitiate the results, the measurements are made differentially, that is, the parallactic displacement of the star is measured not absolutely but with reference to faint distant stars in the background. In practice, the observation consists in securing up to half a dozen photographs at each of five or more epochs of maximum parallactic displacement. The photographs are then measured and the results analysed by introducing three unknowns—namely, a constant, the proper motion and the parallax—and solving by least squares.

But if the apparent motion of the star is not merely a parallactic displacement superposed on a rectilinear proper motion, in particular if the star and an invisible companion are revolving around their common centre of mass, this procedure is not adequate. If it is in fact carried out (as it will be, in a routine observation, since we shall have no *a priori* knowledge of the presence of a companion), the residuals found from the measurements at the various epochs will show a systematic trend. The discovery of periodicities in certain parallax residuals was announced some years ago, but as has been recently pointed out[1], spurious periods of about two years are obtainable from almost all parallax measurements. They are indeed to be expected from general considerations: the method of reduction will tend to balance a large accidental residual at any epoch by residuals of the opposite sign a year earlier and a year later. Some recent work on two frequently observed stars, however, is based on accurate data extending back over some decades, and points very strongly to the presence of companions the mass of which is so small that they would be more accurately described as planets than as stars. It so happens that both these stars are visual binaries, so that the newly discovered companions make them into triple systems.

The system 61 Cygni consists of two sixth-magnitude stars making in 720 years a complete revolution in a large orbit with a semi-major axis of 25 seconds of arc. Extensive photographic observations of high accuracy, made over nearly thirty years, now reveal[2] small deviations from Keplerian motion which can only be explained by assuming that a third invisible component of small mass revolves around one of the main components. If the measurements are reduced on the assumption that the system consists of only two components, residuals are obtained which show a well-marked periodicity both in Right Ascension and in Declination, the period being 4·9 years and the amplitudes about 0·01″. The measurements are made only on the *relative* positions of the visual components A and B, so there is no way of knowing to which of them the perturbing member C is attached. However, the masses of A and B obtained from their known luminosities are practically identical, so that whichever is used in conjunction with the dynamical elements of the small orbit, the same result is obtained: the mass of C is only 0·016 times that of the sun, and the semi-major axis of its orbit is only 2·4 astronomical units (that is, 2·4 times that of the earth). The orbit is so eccentric that at periastron this invisible planet must come within 0·7 astronomical units of its primary. Allowance for the perturbation introduced by the third body removes the systematic trend of the residuals and halves their mean value. We have thus strong evidence for the existence in the 61 Cygni system of a body of mass only about sixteen times that of Jupiter. This is little more than one tenth that of the lightest known star (Krüger 60B, mass 0·14 sun), and the claim that the new companion should be regarded as a planet rather than as a star is evidently very weighty.

The other binary system in which a component of planetary mass has just been discovered[3] is 70 Ophiuchi. This consists of two stars of magnitudes 4·3 and 6·0 revolving in a relative orbit of period eighty-eight years and semi-major axis rather less than 5″. Careful study of photographs taken over a period of nearly thirty years shows periodic deviations from this binary orbit, the observations suggesting a secondary period of seventeen years and amplitudes of about 0·015″ in both X and Y co-ordinates. Again it is impossible to know to which of the main components the perturbing body is attached, but this time A and B are of rather different mass. If the planet revolves around A (mass 1·1 sun) the orbital radius will be 6·8 astronomical units and the mass of the invisible component 0·012 sun. If it is attached to B (0·7 sun) the radius of its orbit will be 5·9 astronomical units and its own mass only 0·008 sun. Here again, then, we have a third body, in what had hitherto been regarded as a binary system, with a mass of about one hundredth that of either of the visual components. In this case the claim of the newly discovered body to be regarded as a planet is even stronger: its mass is only about ten times that of Jupiter.

The state of astronomy is now such that by extending the programme of parallax observations somewhat, invisible planetary companions not much more massive than Jupiter could be discovered if they are in fact attached to the nearer stars. If systematic observations for this purpose were instituted by international co-operation after the War, it could be decided within a relatively short time whether planetary systems are or are not a rare cosmic phenomenon. A definitive answer to this long-standing query would obviously have an important bearing on theories of the origin of our own solar system.

UNITED NATIONS CONFERENCE ON FOOD AND AGRICULTURE

A BRIEF summary of the report and a list of attending delegates and of resolutions passed at the United Nations Conference on Food and Agriculture held at Hot Springs, Virginia, during May 18–June 3 has been published by H.M. Stationery Office*. The Conference was attended by delegations from forty-four countries. The British delegation of nine was under the chairmanship of Mr. Richard Law, Under-Secretary of State for Foreign Affairs.

"The Conference met to consider the goal of freedom from want in relation to food and agriculture. In its resolutions and its reports, the Conference has recognized that freedom from want means a secure, adequate and suitable supply of food for every man."

Freedom from want, the Conference declared, means more than freedom from hunger, but the attainment of the latter is a first essential step towards the attainment of the greater, ultimate good. The Conference recognized that to free the entire population of the world from hunger or malnutrition would require a greatly increased production of foodstuffs, but saw no insuperable technical obstacles to achieving the required level of production. Assuming that such obstacles as have existed in the past could and would be overcome by the technical ingenuity of man, the Conference proceeded to consider the less tractable problems of social and political organizations, on the solution of which the realization of universal freedom from want ultimately depends.

The results of the deliberations are contained in a series of thirty-odd resolutions, the text of which

* Final Act of the United Nations Conference on Food and Agriculture. Cmd. 6451. (London: H.M. Stationery Office, 1943.) 9*d*. net.

comprises the main part of the publication. A full report of the Conference has, apparently, been prepared, and reference is made to it, but it has not yet been published.

The first resolution is in the form of a declaration that the first task of the United Nations, after winning the War, will be to free the peoples of the world from hunger. The full attainment of this goal must be a long process, but essential thereto are greatly increased food production and economic regimes which ensure to all sufficient purchasing power to buy their necessary food. The responsibility that the people have enough food for health and well-being lies with the several nations, but each nation can fully attain the goal only if all work together. The resolutions of the Conference were framed to suggest the kind of machinery that might be set up to promote international collaboration in this vitally important field, and the kind of tasks with which the machinery will have to deal and to which it must be adapted.

The most important resolution of the Conference is that which recommends the setting up of a permanent international organization to promote such measures of food production and agriculture as will raise the levels of nutrition and standards of living of the peoples of the world. Recognizing the urgency of making a start, the Conference recommends the immediate setting up in Washington of an interim commission on which each of the participating Governments was invited to designate a representative before July 15, 1943. The interim commission would automatically dissolve when the permanent commission was established.

The main purpose of the interim commission would be to draw up and submit for the consideration of the participating Governments plans for the form and functions of the permanent organization. It would also formulate a declaration embodying the obligations of each nation to collaborate in the improvement of agriculture and in raising the standard of nutrition. Each Government would be invited to subscribe to this declaration.

The two paragraphs outlining the proposed scope and functions of the permanent organization are important enough to be quoted in full:

> "That in the preparation of a plan for the permanent organization the Interim Commission give full consideration to the following:
>
> (*a*) The relation of the permanent organization to, and methods of associating it with, other institutions, national as well as international, which already exist, or which may hereafter be established, in the field of food and agriculture and in related scientific, economic and other fields;
>
> (*b*) Provision for membership in the permanent organization, in due course, of governments not represented on the Interim Commission;
>
> "That in considering the functions and duties to be assigned to the permanent organization the Interim Commission take into account:
>
> (*a*) The promotion of scientific, technological, social and economic research;
>
> (*b*) The collection and dissemination of information and provision for the exchange of services;
>
> (*c*) The submission to member governments and authorities of recommendations for action with regard to the following:
>
> (i) Nutrition;
> (ii) Standards of consumption of food and other agricultural products;
> (iii) Agricultural production, distribution and conservation;
> (iv) Statistics and economic studies in the field of agriculture and food, including the study of the relation of agriculture to world economy;
> (v) Education and extension work in the field of food and agriculture;
> (vi) Agricultural credit;
> (vii) Problems of agricultural population and farm labor."

A further extension of the functions of the permanent organization into the fields of commodity control, agricultural co-operative movements and land tenure is also tentatively proposed.

It is this permanent organization, to be devised by the interim commission, which will give effect to, or provide the machinery whereby the several Governments can jointly give effect to, the resolutions of the Conference and other measures afterwards designed to bring the ultimate goal of the Conference nearer attainment.

The Conference further recommends that the several Governments should formally declare their intentions immediately to take measures to increase the food resources and to improve the diets of their peoples in accordance with the principles and objectives outlined at the Conference.

The fourth resolution recommends that Governments should undertake positive measures to improve the diets of 'vulnerable' social groups, namely pregnant and nursing women, children and large families in low-income groups.

Resolution V recommends that, whereas a diet at a level merely sufficient to prevent malnutrition is not enough to promote health and well-being, Governments should actively encourage the study of health in relation to nutrition and the dissemination of knowledge of correct feeding. Resolution VI refers to the prevalence of certain deficiency diseases and the need for taking measures to eliminate them and to prevent their recurrence.

Assuming that measures are taken to improve diets and to eliminate deficiency diseases, the Conference recommends (Resolution VII) that national nutrition organizations be established to ascertain the food-consumption habits and nutritional status of different sections of the population, with authority to make recommendations in the light of their findings. Resolution VIII recommends that these organizations periodically and freely exchange information and experience among themselves, and report the results of their investigations to the permanent commission; and Resolution X that the work and experience of organizations already existing for similar purposes should be fully used, whenever possible.

Resolution IX recommends that the goal of food policy in each country should be the optimal diet in quantity and quality, and that Governments should distinguish clearly between this goal and the more immediate goal of minimal diets, at which in many cases they will first have to aim.

Resolution XI recommends that the permanent commission considers questions relating to the production of certain non-food marine and agricultural products, especially those on which some countries ill-adapted to produce their own food depend as a main source of income.

Resolution XII recommends that, as a first step in overcoming the general shortage of food, every effort should be made by countries the agriculture of which can be expanded in the short-term period to increase the acreage under crops for direct human consumption, and even to hold back the rebuilding of depleted livestock herds as well as the production of other crops which compete for acreage with essential foods. This recommendation is made to both those countries where agriculture has, and those where agriculture has not, been impaired by the War. The Conference recognized that the first and most vital task for all will be to eliminate the post-war hunger that will ravage so much of the world. In order to make the best use of the inadequate supplies of food, fertilizers, agricultural machinery, etc., that will be available for some years after the War, it is further recommended (Resolution XIII) that the several Governments affirm the principle of mutual responsibility for the increased production of essential foodstuffs to the utmost capacity of each country, the effective distribution of such foodstuffs, the prevention of speculation in food and other necessities under the anticipated conditions of scarcity, and the gradual adjustment of national agricultures to secure balanced expansion of production and consumption throughout the world.

Resolutions XIV and XV deal with the change-over from a short-term to a long-term agricultural policy. As a working basis the Conference recommends that national farming systems should be adapted to the natural and economic factors of the environment, and should be designed so as to maintain soil fertility and provide steady employment throughout the year. In general, this implies the adoption of mixed rotational farming. The evolution of such systems must be paralleled by the development of programmes of education and research and the provision, where needed, of technical assistance and adequate credit to the producers.

Resolution XVI makes specific recommendations for ensuring an adequate supply of credit to agriculture, and Resolution XVII stresses the importance of establishing farmer co-operative societies in all countries. Resolution XVIII recommends that surveys be made of existing systems of land texture. Resolution XIX enlarges on the importance of providing agriculture with efficient educational, research and technical services.

Resolution XX refers to soil erosion as "the greatest physical danger to the world's food production", and recommends that each nation undertakes the necessary economic and other measures to conserve its soil and water resources, while the permanent commission formulates the principles of soil conservation and facilitates the interchange between nations of conservation experts. Resolution XXI deals with the development and settlement of unproductive lands by drainage, irrigation, soil amelioration, etc. The permanent commission would perform a co-ordinating and controlling function similar to that envisaged in Resolution XX.

Resolution XXII recommends the development of subsidiary industries, internationally controlled emigration, and financial assistance in the intensification of agriculture in regions suffering from rural over-population.

Resolution XXIII recommends in the interest of international security the removal of barriers to the expansion of international trade.

Resolution XXIV makes suggestions for achieving an economy of abundance that read rather like an election manifesto. Resolution XXV recommends that the broad principles be formulated upon which international commodity arrangements should be based in order that such arrangements will contribute to the well-being of the peoples of the world, and proposes that an international organization be created for this purpose and to co-ordinate the operation of such arrangements in accordance with the principles agreed upon.

Resolutions XXVI and XXVII recommend special national and international measures for wider food production, special attention being given to the feeding of "vulnerable" groups and the making available of protective foods to all.

Resolution XXVIII recommends that the permanent commission investigates the practicability, and fosters the adoption, of international grade standards for agricultural and marine commodities with a view to a general improvement in the marketing and quality of food products. A wide extension of market research is advocated, and the taking of steps by the Governments concerned to protect both the producer and the consumer of food against the practices of those who regard them as legitimate prey.

Resolution XXIX recommends that the permanent commission studies the technical, scientific and economic problems of food processing, storage and distribution, and that steps be taken by each country to make full use of new technological processes developed since the War. Resolution XXX urges that the margins between the price to the producer and cost to the consumer be reduced by whatever means are practicable.

Resolution XXXI urges that the conclusions reached by the Conference regarding agricultural produce apply, whenever appropriate, to fish and marine products also, and that these subjects be considered equally by the permanent commission.

OBITUARIES

Prof. Antonín Šimek

FROM a reference in the *Chemisches Zentralblatt* to a notice by Prof. F. M. Jaeger in the *Chem. Weekblad* (August 22, 1943; 39, 454), it is learned that Dr. Antonín Šimek, professor of physical chemistry at the Masaryk University of Brno, Czechoslovakia, must have died about a year ago.

Šimek, who was one of the foremost Czechoslovak physical chemists, was born at Nové Hrady in Bohemia in 1887, and studied at Prague and in Holland, where he made many life-long friends. With the establishment of the Czechoslovak Republic in 1918, he was called to the newly-founded Masaryk University and for many years was fully occupied with the equipment of his laboratories and in academic work, though he found time to conduct researches on tellurium and its oxides. During this work he observed a curious phenomenon that still remains unexplained. He fused tellurium dioxide on electrically heated platinum foil and noticed that the molten drops always move away from the negative pole and towards the positive one. The substance would even travel uphill and its velocity was proportional to the current. In attempting to repeat the experiment with selenium dioxide, which had to be heated under pressure, Šimek met with a serious accident.

Besides being a physical chemist of distinction, Šimek was also a keen mineralogist and he examined a number of Moravian minerals for their content of the rarer elements. Mention has been made of Šimek's connexions with Holland. He also made several visits to England and used English text-books with his students. For their benefit, too, he translated A. S. Russell's "Introduction to the Study of Radioactive Substances" (1925) and Bragg's "Concerning the Nature of Things", and he made a feature of lecturing upon contemporary work in science. Most of his work was published in Czech, but he also wrote in Dutch and occasionally in English journals.

In 1926 he married his assistant, Miss Hannah

Kadlcová, who shared not only his scientific interests but also his devout Protestantism, and both were interested in the Czechoslovak Student Christian Movement.

Šimek, who died at the early age of fifty-five, will be sadly missed when Czechoslovakia is again liberated and the Masaryk University of Brno is re-opened. G. DRUCE.

WE regret to announce the following deaths:

Dr. Mary Jane Rathbun, honorary associate in zoology since 1915 of the U.S. National Museum, known for her work on the Crustacea, particularly the crabs, recent and fossil, on April 4, aged eighty-two.

Mr. H. L. Sikes, C.B.E., formerly director of public works, Kenya Colony, on May 23, aged sixty-one.

BRITISH AND RUSSIAN MEN OF SCIENCE

EXCHANGE OF GREETINGS

THE following message from Prof. Lena Stern, of the Academy of Sciences of the U.S.S.R., to British men of science was transmitted by the Embassy in London of the U.S.S.R. to the Royal Society. With the view of carrying out its intention, Sir Henry Dale, president of the Royal Society, has asked us to publish the message, so that it may reach a wide constituency of those for whom it is intended, together with the reply which he has forwarded to Prof. Stern through the Soviet Embassy.

Message from Prof. Lena Stern

On the day of the second anniversary of the War, I would like to tell you a little of how we Soviet scientists are carrying on to-day, working for our common cause of victory.

In this historic struggle of two worlds, of two world outlooks, of two diametric principles—good against evil, light against darkness, civilization against barbarity—our science has wholly devoted itself to freeing culture from the menace of Hitlerism, to defending the freedom of all nations.

Without exception, all our scientific workers—young and old, men and women—consider it their sacred duty to give all their strength and energy, all their knowledge and their very lives for this cause; and they fulfil their duty sublimely, disregarding all difficulties and all privations which the War has brought in its wake.

The work which is being carried on so intensively at our factories and mills, in our research institutes, in our university departments and in our war hospitals is wholly directed towards helping the front, to perfecting the arms of war, to protecting the health of our fighters. Our science is closely bound up with all the manifestations of the life of the people, both at the front and behind the lines, so much so that it is impossible to divide the man of learning from the fighter, just as it is impossible to divide the research institute from the factory.

It can be said without exaggeration that the heart of the whole people beats in unison with the front and that the slogan "Everything for the front" is not mere words but an actively motivated feeling of the entire people, of our multi-national State.

It is gratifying to be able to state that the theoretical achievements of our science now find wide and successful utilization in the defence of our country and in the strengthening of the fighting powers of our army. Personally I, with my pupils and associates, have since the first days of the War bent all our strength and knowledge to solving problems of the successful treatment of wounded fighters. I am happy beyond words that the results of our many years of theoretical researches now find application in the treatment of such dangerous complications attending injuries as those of shock and tetanus, as well as in accelerating the healing of wounds and the combating of fatigue.

One feels the greatest satisfaction at knowing that by our work to-day we are bringing nearer the hour of our common victory, bringing nearer the advent of peace under which creative work will be able to develop to its full force.

We must all remember that our peaceful, constructive endeavours, the labour of free men of science, can be ensured only by complete victory over the enemy. I believe this victory will come as the result of the joint offensive by the Allied Armies.

Warmest greetings to you, my friends.

Moscow, June 27. LENA STERN.

Reply by Sir Henry Dale, G.B.E., F.R.S.

The receipt of your message to British men of science has given great joy, and reminded me of my friendship with you, and our work together for international science, before the enemies of mankind inflicted on the world its present miseries, by their ruthless attack on the freedom and civilization of independent peoples.

Your stirring message came to me as president of the Royal Society of London, and, on behalf of all British men of science, I most heartily reciprocate your greetings and encouragement. We send to all the scientific workers of the U.S.S.R. an assurance of our full union with them, and with the men of science of all the great alliance, in a strong and fierce determination to use the utmost measure of our knowledge, skill and devotion to ensure and hasten the utter defeat of the enemies of freedom. We are equally determined that, with that defeat, conditions shall be established beyond danger of further attack, in which the scientific men of all nations may work for the greater happiness and health of all mankind.

Tell our comrades, the scientific workers of the U.S.S.R., that we, the scientific workers of Britain and of all the British Commonwealth, have been wholeheartedly devoted to these aims and these ideals during nearly four years of war, and with continued enthusiasm and growing confidence during these two years, in which we have known that our colleagues of the U.S.S.R. were our open and devoted allies in this tremendous war for freedom. We watch with unbounded admiration the achievements of the armies, workers and men of science of the U.S.S.R. for the common cause. We rejoice to know that we are marching together for the freedom of science and of the world.

With my friendliest personal greetings to yourself, and from all British men of science to all those of the U.S.S.R. HENRY DALE (President).

Royal Society, July 7.

NEWS AND VIEWS

Department of Scientific and Industrial Research: New Director of Food Investigation

DR. CHARLES S. HANES, who has recently been appointed director of food investigation in the Department of Scientific and Industrial Research, was born in Canada in 1903 and graduated at Toronto. He entered Downing College, Cambridge, in 1925 as a Junior 1851 Scholar and was awarded a Senior Scholarship in 1929. He obtained the Cambridge Ph.D. degree in 1931. He was a research fellow of the Ontario Research Foundation during 1931–35, in which year he joined the staff of the Department of Scientific and Industrial Research at the Low Temperature Research Station, Cambridge. In 1942 he was elected a fellow of the Royal Society.

Hanes's first published paper was on resin formation in seedling conifers (*J. Linn. Soc.*, 1927), and his subsequent papers have dealt with various phases of carbohydrate metabolism, more especially the action of the enzymes involved in carbohydrate breakdown and synthesis. The culminating point of his researches (to date) was the "Enzymic Synthesis of Starch from Glucose-1-Phosphate" (NATURE, **145**, 348; 1940). Hanes thus achieved the production of starch from sugar as a laboratory process. In collaboration with W. T. Astbury and F. C. Bell, Hanes showed that synthetic starch was indistinguishable by X-ray analysis from natural starch (NATURE, **149**, 558; 1940) In 1941 Hanes was sent by the Department of Scientific and Industrial Research to Canada and the United States with the object of facilitating the exchange of scientific and technical information relating to the preservation of foodstuffs. Later he was lent to the Ministry of Food for service with the British Food Mission in Washington. On the formation of the Advisory Committee on Dehydration of the Combined Food Board, Hanes became its chairman.

Johnston Chair of Biochemistry at Liverpool: Retirement of Prof. H. J. Channon

PROF. H. J. CHANNON, who is leaving the Johnston chair of biochemistry in the University of Liverpool at the end of the present academic year to take up an appointment with Unilever Ltd., is a recognized authority on fats and fat metabolism. After graduating in both arts and science from University College, London, he worked in the biochemical department there, either alone or with various colleagues, on the biological significance of the unsaponifiable matter of various liver oils, on cholesterol metabolism and on the nature of the lipoid constituents of cabbage leaves. This latter research led to the isolation of two new interesting compounds, diglyceride-phosphoric acid and dimyristyl ketone. Throughout this period he displayed a marked keenness for teaching as well as for research, and on being called to succeed Prof. Ramsden at Liverpool in 1930 he was able to give full vent to both these urges.

Giving at first a priority to teaching, Channon reorganized the biochemistry courses for the medical students and particularly for those taking the B.Sc. degree in the subject; his efforts here have undoubtedly borne fruit, and until the inevitable interruption by the War, a steady stream of well-trained graduates came from his department to find employment in academic research or in industry. Many collaborated with him in his own researches, which dealt *inter alia* with the fate of injested hydrocarbons, the desaturation theory of fatty acid metabolism and the effects of various factors in the production of dietary fatty livers. A clear and convincing speaker in lecture or discussion, Prof. Channon's transfer to industry will leave a gap in academic circles that will be hard to fill. He leaves, nevertheless, with a wide experience of research on fats and related substances which should enable him to make the fullest use of opportunities that lie ahead, and his former colleagues will wish him all success in his new venture.

Future of the British Colonial Empire

AN important statement on the future of the British Colonial Empire was made in the House of Commons on July 13 by Colonel Oliver Stanley, Secretary of State for the Colonies. Colonel Stanley said that the foundations of political responsibility in the Colonies must be based on the twin pillars of educational advance and economic development. The Colonial universities would have an important part to play in advancing higher education; they would have to produce leaders, and also do an increasing amount of research. The universities of Great Britain can help in this development, and the institution of a kind of lend-lease intellectual service between them and the universities of the Colonies would result in many advantages to both parties. A commission of inquiry under the chairmanship of Sir Cyril Asquith is being set up to consider how this co-operation can be best achieved. Another commission, under Mr. Walter Elliot, will consider higher education in British West Africa; African representatives of the areas involved have been invited to serve on this commission.

Dealing with the more general topics of economic development and administration, Colonel Stanley said the work of labour advisory boards has enabled the two sides of industry to meet and has encouraged the principle of collective bargaining. Some three hundred trade unions are now in existence in the Colonies. It is hoped to open a course, extending over two years, at the London School of Economics, on training for leadership in societies, and open to people from the Colonies, and particularly Africans and West Indians. So far as development is concerned, Colonel Stanley said that a special department is being created in the Colonial Office to deal with communications, and special interest is being taken in air transport. Industrial development will, he believes, depend upon private enterprise, under proper control.

In replying to the debate, Colonel Stanley added an important note on Colonial administration. He said that while the Government is convinced that such administration must continue to be the sole responsibility of Great Britain, it is desired to work in close and friendly co-operation with neighbouring and friendly nations. To this end, the Government is considering the possibility of establishing commissions for certain regions, these commissions to consist of representatives of States with Colonial territories in the region and of other States with major economic or strategic interest therein. Each State would remain responsible for the administration of its own territory, but such commissions would provide permanent machinery for collaboration in promoting the welfare of Colonial territories generally. Colonial peoples would be associated with the work of the commissions. The formation of such commissions would be a great step forward in promoting the international recognition of trusteeship, as opposed to ownership, of Colonial territories.

Aspects of Demobilization

THE important address of Sir William Jowitt to representatives of municipal and business interests of Merseyside, delivered in Liverpool on June 17, directed attention to a vital but complex aspect of post-war reconstruction. The complexity of the problems of demobilization should be apparent to all, but Sir William Jowitt's remarks on the subject were reassuring in that he said that the fatal mistakes of 1918–19 will not be repeated. Sir William urged that it would be foolish to involve members of the Fighting Forces in any controversy about rival schemes of demobilization ; past experience justifies the reminder that it would be highly dangerous. The very difficulty of devising a fair and efficient scheme of demobilizing in the shortest possible time a huge number of men and women and resettling them in peace-time work in industries, most of which would be short of raw materials, while many of the factories would require re-tooling and re-arranging, makes it imperative that a policy should be decided upon promptly and that it should be explained intelligently as soon as possible to prevent misunderstanding later on. Sir William Jowitt stated that the Government has adopted a scheme in which the guiding factors are age and length of service. Clearly, however, demobilization cannot be based entirely on these principles. The necessity for armies of occupation, apart from the probability of the war with Japan continuing after Germany has been defeated, will involve a partial demobilization, and the release of men may have to be determined to some extent on transport grounds, for example. Similar considerations may apply to industry. A more orderly transition from war to peace than in 1918 means that some workers will be more urgently required than others when peace-time industry is starting up and the process of re-equipment and reconstruction commences.

The *Economist* has indicated some broad principles of industrial demobilization that merit consideration. Capacity capable of working directly for export should be freed from war obligations as soon as possible. Food, clothing and shelter should come before luxuries. Industries capable of being reconverted to peace work without expensive re-equipment and re-tooling should be allowed to turn over as soon as practicable, to economize the resources needed for immediate reconstruction. British demobilization, both of machines and men, should be an integrated part, not only of the continuing war effort of the United Nations, but also of the joint plans made by them for relief and reconstruction on a world scale. The service of such principles leaves no room for pointless argument, but equally it demands of the Government prompt decisions which must be made known and fully explained. In demobilization—and indeed in reconstruction generally—the channels of assent can never be dug too deep if acrimony is to be avoided.

Association of Teachers in Technical Institutions

AT the annual conference of the Association of Teachers in Technical Institutions, held in London during Whitsuntide, Mr. J. C. Hazelip of the Leeds College of Commerce was inducted as president of the Association. It is some fifteen years since a teacher of commerce was elected to the office. In his presidential address Mr. Hazelip referred to the additional work undertaken by technical colleges during the War. It includes training of R.A.F. and Royal Navy personnel in radio work and of the R.A.O.C. and the R.E.M.E. for the many maintenance jobs which a mechanical army needs in the field. There is also the training of members of the A.T.S for clerical and other work. Mr. Hazelip stressed the importance of this contribution by the technical colleges to the national war effort "since success in modern warfare is largely a matter of being in possession of the necessary equipment and of the technical skill to keep it in working order". Thus, he said, the work of technical education is an important factor in bringing the present struggle to a successful issue. He stressed, too, the fact that this additional work had gone on "without interference with normal technical college activities". With the possibilities of an Education Bill in mind Mr. Hazelip sketched arguments against merging junior technical and commercial schools into a "multilateral school". Technical education, he said, must be conducted in an atmosphere of realism and must be able to call upon the services of men and women who themselves had experienced the difficulties and problems "inherent in the spheres for which the students are being prepared educationally". Technical education must be dovetailed into the industrial and commercial life of the community round it. This realistic atmosphere, he said, could not be found in the normal secondary school. He insisted, however, that notwithstanding the realism of its approach, the junior technical school in its work in English subjects, science and foreign languages, would stand comparison with any similar work now being carried on in any other type of post-primary school.

War Background Studies

No. 7 of the series of Smithsonian Institution War Background Studies, by J. F. Embree, is devoted to an account of the Japanese nation, its origins and present social structure. The reader is assumed to have some familiarity with Japanese art and literature, costume and types of building. The economic framework of the lives of the people is only very briefly touched upon, and nothing is said about the physical geography or climatic conditions of the country. On the other hand, nearly half of the 36 pages are devoted to the family and household structure and to the customs surrounding the events of the individual life from birth to death, and there is a short chapter on religious beliefs. The author is of the opinion that the obvious differences between the mental processes of adult Japanese and Americans are solely the result of these customs, outlook, and beliefs. Perhaps the most helpful and charming feature of this brochure is its sixteen excellent photographic plates.

No. 8 of these Smithsonian pamphlets, by H. G. Deignan, gives an account of Siam and its inhabitants. In this case a description of the geographical setting is given, and the whole work might be considered as an introduction, but little more, to what would indeed prove a very interesting study. The region dealt with can be divided into a northern, an eastern and a central area, the latter passing down southwards into the Malay peninsula to the frontier of the Straits Settlements. The aboriginal Negrito popula-ion can to-day only be found in isolated groups in he hills: at least three migrations from the north aving at various times overrun the land. It was ut a few centuries ago that a number of petty ingdoms arose, and only comparatively recently hat what can be called a real national feeling has eveloped. Siam is a country little known to the verage white man. It merits somewhat more etailed treatment than has been possible in these 8 pages. The illustrations, once again, are delightful.

Work of the Tennessee Valley Authority

THE article "T.V.A. An Achievement of Democratic Planning", by Dr. Julian Huxley, which occupies the greater part of the June number of *The Architectural Review,* should be of wide interest in view of the absence in Britain of adequate descriptions of the work of the Tennessee Valley Authority. This concise but comprehensive account of T.V.A. in all its implications, which is illustrated by many photographs, most of them new, gives a striking demonstration of the possibilities of judiciously and democratically applied regional planning. The article is timely, for in the post-war planning which must be undertaken in Great Britain we cannot afford to neglect the experience gained in ten years work on the world's boldest venture in regional reconstruction. Moreover, Dr. Huxley includes a critical examination of the limiting conditions of such democratic planning and stresses the essential characteristics: the making of the greatest number of decisions on the spot; development so far as possible of the active participation of the people themselves; co-ordination in the field of the work of all the other agencies concerned; and decentralization of the idea behind an administration so that its planning becomes a part of public opinion. The provision of full powers for a limited function with the organization developed, and the special methods of survey and system of research deliberately adjusted to consumer needs, are all new tools, as Dr. Huxley points out, which will be of service to any democracy in its struggle to control its own social destiny.

Scientific workers will be particularly interested in Dr. Huxley's concise account of research carried out by the Tennessee Valley Authority. In its chemical laboratories a method has been worked out for extracting aluminium from certain common types of clay, which has reached the pilot plant stage, and work on the extraction of magnesium from olivine is also coming to the pilot stage. In the biological field, valuable research has been carried out on malaria control, the incidence of malaria and the encouragement of fish life. The most important aspect of its agricultural research is concerned with the prevention of erosion, including the growing of new cover-crops, while the investigation devoted to the perfecting of agricultural machinery is an excellent example of research carried out and applied from the point of view of consumer interests. This has led, for example, to an electric hay-drier, costing less than 10 per cent of the previous cheapest drier on the market, and a cheap furrow seeder. Elaborate experiments have been conducted to discover suitable trees and shrubs which will yield crops of fruit or nuts suitable for direct human consumption or available for pigs or other animal stock. Much research has been put into the development of a new type of pressure-cooker for producing cotton-seed meal and oil. Other research has led to the development of quick-freezing machinery suitable for use by farmers' co-operatives, which has much increased the growing of various fruit crops. The planned surveys of the Authority are of equal interest, and a new type of land classification has been worked out with the co-operation of the National Resources Planning Board; and a land-use survey has also been prepared for the most important areas of the Tennessee Valley.

Aid for Chinese University Students

THE International Student Service Committee in Chungking is a constituent member of the National Student Relief Committee, which works in close co-operation with the Chinese Government and enjoys the full support of the United Aid to China Fund in Great Britain. Among other schemes, the National Student Relief Committee has organized a system of national scholarships, under which two hundred select students receive free maintenance, university education and constant tuition. The International Student Service Committee in Chungking has made itself specially responsible for the creation of a student centre at Shapingba, near Chungking, for refugee students from the occupied zones, and from all parts of Free China. A large percentage of them is homeless and penniless; others receive small grants for food, books, clothes and university fees. A well-stocked library is maintained for them; discussion groups are run on many subjects, including economics, diplomacy and current international topics.

The International Student Service in Great Britain (11D, Regent Street, London, S.W.1) has during past years sent out regular appeals in aid of the universities of China. It has been able to send out more than £1,000 annually, and hopes to be able to continue this assistance. Any amount collected is now being passed on to the United Aid to China Fund, which has promised to transfer the donations and to make recommendations to Madame Chiang Kai Chek, in whose hands lies the allocation of funds in China. Further information concerning its activities in this connexion can be obtained from the Secretary of the Service, at the above address.

Protection from X-rays and Radium

THE revised edition of the recommendations of the British X-Ray and Radium Protection Committee (32 Welbeck Street, London, W.1) embodies no drastic changes from the previous issue of this report. Certain precautions have been made more precise, and data relating to more powerful X-ray apparatus and larger quantities of radium used as mass units have been included. Thanks to these recommendations, the extension of irradiation methods into industrial practice should not be followed by an increase in the band of X-ray martyrs who suffered during the early years of the introduction of these methods into medicine. Attention is directed in the report to special Defence Regulations relating to the precautions to be observed by all those engaged in painting objects with radioactive fluorescent mixtures. Although reference is made to the desirability of systematic blood-tests and the measurement of the concentration of radon in expired air, it is strange that no recommendation is made for the periodical inspection of the hands of persons habitually engaged in the manipulation of radioactive preparations or containers. Another apparent omission is the neglect to direct attention to the dangers attending the surgical use of diathermy apparatus in the presence of ether vapour. The thanks of all workers in the field of radiology throughout the world are due to the British X-Ray and Radium Protection Committee for its pioneer and continuing labours in this field.

Vitamin C Content of Oranges

IN the issue of the *New England Journal of Medicine* of January 7, Dr. Arthur D. Holmes, James A. Patch and Francis Tripp of the Research Laboratories of E. L. Patch Co., Stoneham, Mass., record their observations on the relation of season, weight and price to the vitamin C content of oranges. They found that there was considerable seasonal influence on nutritive value, the oranges being heavier and containing more juice at a lower vitamin C cost in December than at any other seasons of the year. The cost of 75 mgm. was 4·8 cents in March, 5·9 cents in June and September and 3·6 cents in December. The average purchaser, therefore, cannot use the size or cost of oranges as a reliable guide to the amount of juice or to the cost of the daily requirements of vitamin C.

New Zealand Earthquakes

DURING March 1943, fifteen strong earthquakes were registered by the seismographs at Auckland, Arapuni, Bunnythorpe, Christchurch, Kaimata, New Plymouth, Tuai and Wellington, all stations participating in the New Zealand Seismological Service and sending records or readings to the Dominion Observatory at Wellington (New Zealand Seismological Report—Provisional Bulletin, No. *P* 133, 1943, March). The records are remarkable in that eight of the shocks had a depth of focus greater than normal. The first, on March 4, had an epicentre south of Fiji and a depth of focus near 600 km. The shock of March 11 with epicentre east of New Caledonia had a depth of focus near 100 km. Earthquakes on March 15 and 21 have already been reported in NATURE, the data coming from the U.S. Coast and Geodetic Survey. On March 26 a very strong earthquake with an epicentre south-east of Tonga had a focal depth of between 80 and 100 km. It was reported to have been felt at Nukualofs, according to a message from Apia. The earthquake gave very large amplitudes on the vertical components of seismographs. Further, there was minor seismic activity, and 22 earthquakes or earth tremors were reported as having been felt (additionally) in New Zealand. The greatest of these shocks was Scale VI on the Modified Mercalli Scale. It occurred on March 14 and was felt in the southern part of South Island. Two earthquakes were felt with Scale V intensity. The first, on March 1, was felt from Te Kuiti and Waipawa to Greymouth and Rakaia. The second, on March 25, was felt at Westport. One shock was felt with Scale IV intensity and the rest with lesser intensities.

Earth Tremors in Portugal

EARTH tremors accompanied by earthquake noises were reported from Oporto, Braga and Viana do Costelo in north Portugal to have taken place on the night of June 22. Although these tremors caused some apprehension, they did not last long and no serious damage has been reported.

Centenary of the S.S. *Great Britain*

ON July 19, 1843, in the presence of the Prin Consort, the famous *Great Britain* was floated in t dock at Bristol in which she had been under co struction for four years. As the first iron ship bu for the Atlantic traffic, as the first ocean-going scre ship, and as by far the largest iron ship built to that time, she stands out as a magnificent specim of the art of shipbuilding as carried out by fa sighted, energetic and unprejudiced men. She w 322 ft. long, 50½ ft. wide and at a draught of 18 had a displacement of 3,618 tons. The credit f her construction belongs to Captain Christoph Claxton, R.N., secretary of the Great Western Stea ship Co., the famous engineer I. K. Brunel, Willia Patterson, a Bristol shipbuilder, and Henry Richa Guppy, another Bristolian who afterwards did go engineering work in Italy. When completed in 184 the *Great Britain*, after being visited by Quee Victoria, took her place beside the *Great Western* o the Atlantic and made several crossings. Unfortu nately, in September 1846 she ran ashore in Du drum Bay, Co. Down, but was salved a year late She was refitted as an auxiliary screw ship, and f many years employed on the Australian run. I 1882 she was converted into a sailing ship. He active service came to an end four years later, whe after a severe buffeting off Cape Horn she put int Port Stanley, Falkland Islands, where she becam a wool hulk. Up to 1938 at least, she was still so used an eloquent testimony to the quality of her iron hul and the workmanship of the Bristol shipbuilders.

National Research Council, Canada : Scholarship

THE National Research Council, Canada, announce the award for the academic year 1943–44 of 14 fellowships of the value of 750 dollars each, 30 studentship of 650 dollars each and 21 bursaries of 250 dollar each. The sixty-five successful candidates for thes post-graduate scholarships comprise graduates o fifteen Canadian universities, and they will carry ou research work in the coming year at eleven of thes institutions. As a result of war conditions, the field of science in which the scholarship holders will wor are reduced in number as compared with a few year ago. By far the greatest number will work in variou branches of chemistry related to the war effort According to a general classification adopted i announcing the awards, 49 will study chemistry 6 physics (including one radiology), 4 biochemistry 2 genetics, and one each biology, mineralogy, mechanical engineering and electrical engineering.

Announcements

THE following have been elected officers an members of council of the Institution of Electrica Engineers for the year 1943–44 : *President :* Sir A Stanley Angwin ; *Vice-Presidents :* Mr. T. G. N Haldane, Dr. E. B. Moullin ; *Hon. Treasurer* Mr. E. S. Byng ; *Ordinary Members of Council* Brigadier F. T. Chapman, Mr. J. Hacking, Mr. A. L. Lunn, Dr. J. L. Miller, Mr. J. S. Forrest, Mr. E. C. S. Megaw, and Mr. E. Leete.

WE have received a copy of the revised pamphlet "Photography as an Aid to Scientific Work" from Ilford Ltd., Ilford, London. This gives lists o plates, films and papers suitable for all branches o scientific work, including medicine and surgery, clinical photography and radiography. There are also notes on filters and darkroom safe-lights.

Factorial Analysis of Physical Growth

The 'Harvard growth study'[1], based on measurements of the same children year after year, is a type of co-operative research which urgently needs repeating in Great Britain. There are, however, one or two conclusions to be drawn from the American data which the investigators themselves seem to have overlooked. Until recently, it has been commonly supposed that there is no general factor entering into physical growth analogous to the general factor entering into mental growth[2], and no convincing evidence for the existence of group-factors, distinguishing human body-types, analogous to the well-established group-factors found in work on temperament, mental imagery, and the like (ref. 1, p. 291 and refs.). That physical development should proceed so differently from mental development would be somewhat surprising; but a glance at the literature shows that statistical methods adopted by Kretschmer, Spearman, and others in studying relations between physical measurements were scarcely as adequate as those now employed to establish mental types and mental factors in the field of individual psychology.

On applying the newer technique of 'multiple factor-analysis' to physical measurements, obtained from groups of English school children and students, I found strong *prima facie* evidence both for a general factor and for type-factors[3]. Similar results have since been obtained with groups of a different racial composition: Dr. J. I. Cohen, at my suggestion, analysed measurements for a Jewish sample, and reported the results in these columns[4]; more recently, Mr. W. H. Hammond has reached the same conclusions with measurements collected from Welsh adults by Prof. H. J. Fleure and from Irish adults by Mr. Mogey[5]. But perhaps the most interesting confirmation of all is to be found in the Harvard data, where correlations are available for a far larger group, comprising more than five hundred 16-year-old American youths (ref. 1, p. 301). On applying the same technique as before, I find, first a general factor accounting for more than 60 per cent of the total variance, and secondly a bipolar factor distinguishing persons showing relatively excessive growth in 'vertical' directions (height, length of leg, arm, or trunk) and those showing relatively excessive 'transverse' or circumferential growth (iliac width, chest width, chest depth, weight). The second factor points to much the same distinction as that drawn by earlier French and Italian physiologists, and popularized by Kretschmer's work on psychotic patients, namely, the distinction between asthenic, leptosomic, or microsplanchnic types and pyknic, eurysomic, and megalosplanchnic types respectively.

The confirmation is the more remarkable because the American investigators themselves regard their measurements as "illustrating the futility of trying to describe any but extreme cases as types". Like so many, however, they interpret 'types' as implying sharply discriminable classes rather than relative or partial tendencies; and they make no attempt to eliminate the obscuring influence of the more powerful 'general factor'. How far the so-called types may be due to racial, genetic, or endocrinological 'factors' is a question which statistical analysis alone is not competent to determine. It may be added, however, that the discovery of factors of two kinds, one influencing size, the other proportion or shape, is fully consistent with the distinction between isogonic and heterogonic growth in lowlier animals[6] and with the theory of two fundamental forms of growth recently put forward by Smalhausen at the Institute of Experimental Biology at Kiev.

Semi-conducting Properties of Stannous Sulphide

Semi-conducting properties of metallic oxides have received considerable study in recent years and have contributed largely to the theory of defect structures. By comparison, little attention has been paid to the heavy-metal chalcogenides, although their pronounced semi-metallic properties (for example, lustre, very high conductivity) suggest that among them, if anywhere, might be found the intrinsic Wilson semi-conductors[1]. In this connexion, a special interest is attached to such compounds as lead sulphide and stannous sulphide, in which the cations possess unutilized valency electrons, which might well contribute to the metallic conduction. With this in mind we have studied the conducting properties of stannous sulphide, and present here our main conclusions. A fuller account and discussion of the experimental data will be published elsewhere.

In agreement with an isolated measurement by Tubandt[2], stannous sulphide is an electronic conductor at all temperatures. Even at the highest temperature investigated (750° C.), the ionic component of the conductivity certainly does not exceed 1 per cent of the total conductivity. Preliminary observations show that no pronounced increase in conductivity accompanies fusion (melting point of stannous sulphide, 870° C.), so that the liquid is probably a semi-conductor also.

Variation of conductivity with temperature can be represented by a two-term formula

$$\varkappa_{I_s} = Ae^{-E_1/RT} + Be^{-E_2/RT}.$$

The high-temperature conductivity is reproducible from one specimen to another, and independent of past history; $E_1 = 12{,}600$ cal. This presumably corresponds to intrinsic semi-conduction. At lower temperatures (for example, below 300°), impurity conduction supervenes, and the manner in which the number of conducting centres and the activation energy E_2 depend on the previous treatment of each specimen indicates that under these conditions positive hole conduction takes place, in a non-stoichiometric crystal.

This may be exemplified by the accompanying data. Treatment of one particular specimen with pure hydrogen increased R_{18° almost 2,000-fold. Exposure at the ordinary temperature to air, or to hydrogen containing a trace of oxygen, or reaction with hydrogen sulphide, led to a rapid increase of conductivity. This clearly points to the taking up of oxygen or sulphur which, once incorporated in the crystal as oxide or sulphide ions, can be removed only by reduction at temperatures above 300°.

We infer that stannous sulphide is non-stoichiometric, with a range of composition on the sulphur-rich side of the ideal formula. In accord with the variable valency of tin, a certain proportion of tin atoms are raised to a higher valency (on energetic grounds trivalency appears more likely than quadrivalency, although no compounds of trivalent tin exist), and a corresponding number of cation sites are left vacant. Each such positive hole is potentially a conducting centre, which can migrate through the lattice by switches of the excess charge from cation to cation. Assuming a reasonable value for the mobility of an electron in stannous sulphide[3], our figures indicate that 'equilibrium' stannous sulphide, that is, stannous sulphide exposed to oxygen, or heated in hydrogen sulphide to 300°, contains between 1 in 1,000 and 1 in 100,000 excess anions. At ordinary temperatures this confers a conductivity far outweighing the intrinsic conductivity, since the conduction band lies about 0·55 volts above the highest occupied level.

Treatment of Stannous Sulphide	R_{18° ohms	K_{18° mhos	E_s, cal.
Exposed to air. $pO_2 = 152$ mm.	288	$1 \cdot 1 \times 10^{-2}$	3200
Reduced in pure hydrogen at 350°	501,000	$6 \cdot 8 \times 10^{-6}$	8300
Exposed to cylinder hydrogen, $pO_2 = 0 \cdot 76$ mm.	1,100	$2 \cdot 9 \times 10^{-3}$	5100
Exposed to poor vacuum, $pO_2 < 0 \cdot 1$ mm.	13,600	$2 \cdot 4 \times 10^{-4}$	5500
Treated with hydrogen sulphide at 300°	288	$1 \cdot 1 \times 10^{-2}$	3200

Reaction between Long-Chain Cation-active Salts and Sodium Hexametaphosphate

DURING an investigation involving the use of cation-active salts such as cetyl pyridinium bromide in conjunction with sodium hexametaphosphate, it was observed that precipitates frequently occurred. Further observations on distilled water solutions showed that cation-active long-chain salts of this class give rise to intense turbidity and in some instances to complete precipitation when treated with sodium hexametaphosphate ("Calgon").

The nature of the insoluble complex is not known, but other phosphates such as Na_3PO_4, Na_2HPO_4 and NaH_2PO_4 are without effect. Tetra sodium pyrophosphate gives a slight turbidity.

The literature appears to contain no record of such a reaction, and it is therefore mentioned because of its possible importance in connexion with textile processes where such auxiliaries are sometimes used. It may also have some value in relation to the more academic aspects of the sequestering power of sodium hexametaphosphate.

I am indebted to the Director of Research for his guidance, and to the council of the British Launderers' Research Association for permission to publish this note.

The Donnan Membrane Equilibrium

WHEN applying the distribution law of Boltzmann to the Donnan membrane equilibrium in two compartments, one containing a mixture of colloidal ions (or non-diffusible ions) and electrolytic solutions and the other electrolytic solutions, we have to assume the compartment containing the colloid or non-diffusible ions to consist of a charged material and a double layer, which extends up to the membrane through which the colloidal particles or non-diffusible ions cannot pass. In the case of colloidal solutions, the membrane may also be considered as a plane, separating the double layer and the bulk of the solution through which the colloidal particles cannot pass. The membrane potential, E_m, might be put equal to $\psi_1 - \psi_2$, where ψ_1 is the potential of the ion positive or negative in compartment 1, containing the colloid or the non-diffusible ion, and ψ_2 is the potential of the same ion in the other compartment 2.

We have, therefore, at all values of the membrane potential,

$$q_+ (c_+)_1 + q_- (c_-)_1 = \{q_+ (c_+)_2 + q_- (c_-)_2\} \cosh \frac{N^* E_m F}{RT} \qquad (1)$$

or

$$(c_+)_1 = (c_+)_2 \cosh \frac{N^* E_m F}{RT} ;$$

where $(c_+)_1$ and $(c_-)_1$ are the concentrations of positive and negative ions in compartment 1, and $(c_+)_2$, $(c_-)_2$, the corresponding concentrations of ions in compartment 2;

$$c_+ \text{ is } \frac{q_+ (c_+) + q_-(c_-)}{q_+ + q_-}$$

$$\text{or } \{(q_+ c_+)^{q_+} (q_- c_-)^{q_-}\}^{1/(q_+ + q_-)}$$

and q_+, q_- are the numbers of positive and negative ions; and F is one faraday of electricity, R the gas constant, T the temperature, and $N^* = N_1 = N_2$ or $(N_1 N_2)^{1/2}$.

When $\frac{N^* E_m F}{RT}$ is much less than unity,

$$q_+ (c_+)_1 + q_-(c_-)_1 = q_+ (c_+)_2 + q_-(c_-)_2 \quad . \quad (2)$$

$$\text{and } \left(\frac{N^* E_m F}{RT}\right)^4 \leqslant \left(\frac{N^* E_m F}{RT}\right)^2$$

$$q_+ (c_+)_1 + q_-(c_-)_1 = \{q_+ (c_+)_2 + q_-(c_-)_2\} \left\{1 + \tfrac{1}{2}\left(\frac{N^* E_m F}{RT}\right)^2\right\} \quad (3)$$

The membrane potential is small when calculated from mean concentrations of ions, and the equation

$$(c_\pm)_1 = (c_\pm)_2 \quad . \quad . \quad . \quad . \quad (4)$$

can be deduced from equation (1).

The data of Rinde[1] on sulphur sols, of Azume and Kameyama[2] on congo red and Mattson[3] on bentonite systems show that the relations (1), (2) and (3) hold with accuracy. The relation (4) holds with much greater accuracy.

In considering the equilibrium between ions and undissociated molecules in solutions of weak electrolytes, the solution may be assumed to consist of two compartments in one of which there are undissociated molecules and ions, and in the other only ions. The uncharged solute species cannot pass into the double layer (ionic atmosphere) and therefore the principle of Donnan membrane, equilibrium is applicable. From the equilibrium

$$\begin{tikzcd}
\text{Undissociated molecules} \arrow[d, shift left] \arrow[dr, shift left] & \\
\text{Double layer} \arrow[u, shift left] \arrow[r, shift left] & \text{Bulk} \arrow[l, shift left, "\text{(Debye)}"] \arrow[ul, shift left, "\text{(Ostwald)}"']
\end{tikzcd}$$

we have

$$K = \frac{(c_{\pm})^2{}_D}{c(1-\alpha)}$$

between the undissociated molecules and the double layer, where K is the equilibrium constant, and c the concentration of the electrolyte with conductivity coefficient α and $(c_{+})_D$ is the mean concentration of ions in the double layer. The concentration of ions in the double layer may be found from the distribution law of Boltzmann and

$$K = \frac{c\alpha^2}{1-\alpha} \cosh^2 \frac{N^* E_m F}{RT} \quad . \quad . \quad . \quad . \quad (5)$$
$$= \frac{c\alpha^2}{1-\alpha} \text{ when } \left(\frac{N^* E_m F}{RT}\right)^2 \ll 1,$$

which is Ostwald's dilution law. Equation 5 is the new dilution law from which Ostwald's dilution law can be deduced

Relation of Tea 'Fermentation' to Normal Respiration

IN a recent communication, Sreerangachar[1] has criticized certain of my conclusions as to the relationship existing between the process known as tea-fermentation and the normal respiratory mechanism of the tea-leaf. In view of the somewhat divergent conclusions drawn by this author and myself[2], some further discussion of the results is desirable. Unfortunately such criticisms as are made cannot be backed up by further experiment until we are able to return to our normal peace-time activities.

The fundamental criticism made by Sreerangachar is that neither mechanical rolling nor fine mincing is sufficient to result in the disruption of every cell in the tissue, so that the fermenting leaf must be considered as a heterogeneous mixture of damaged and undamaged tissue. The implication is that in such crushed tissue some respiratory activity will persist.

Sreerangachar then goes on to describe experiments which show that finely minced tea-leaf, as obtained in his laboratory, is in fact a heterogeneous mixture of respiring and 'fermenting' tissue, and that further damage increases the $-Q_{O_2}$ and still further depresses the *R.Q.* He also succeeds in achieving some separation of the fermentation and respiration processes by washing the minced tissue with water. The washed tissue shows practically no fermentation, and as the carbon dioxide outputs of washed and unwashed tissue are not dissimilar he concludes that the carbon dioxide output in the minced tissue is largely contributed by undamaged cells.

This conclusion neglects the possibility that free polyphenols, or their oxidation products, may depress normal respiration and hence carbon dioxide outputs. In finely chopped tissue the carbon dioxide may then originate partially through carbohydrate oxidation with *o*-quinones as the hydrogen-acceptors, and partly as a result of inhibited normal respiration. It is by no means unlikely that the carbon dioxide produced by these two mechanisms will differ but little from that produced by uninhibited respiration in the intact portions of the tissue in the washed material.

Sreerangachar's experiments in which glucose is added, without effect, to an *in vitro* enzyme-substrate mixture have no bearing on the problem, as an enzyme obtained by the action of acetone on tea-leaf tissue would certainly lack many of the factors required to bring about oxidation of glucose by *o*-quinones.

Although it is admitted that Sreerangachar has demonstrated that his minced tissue preparations contain some undamaged tissue in which normal respiration persists, his claim that carbon dioxide evolved from crushed tissue comes only from undamaged cells is by no means firmly established. As shown above, an alternative explanation of these results can be advanced. In addition it may be pointed out that his own figures show, like my own, a rapid drop in carbon dioxide output after the first forty-five minutes. If carbon dioxide were a product solely of respiration one would expect the output to be maintained at or near its original level. A period of constant output followed by a rapid fall to an almost zero level is difficult to explain on Sreerangachar's hypothesis.

It has never been my belief that fermentation takes place only in completely ruptured cells. Damage such as is inflicted during mechanical rolling in manufacture is insufficient to destroy the cellular nature of the tissue, yet fermentation may take place to the extent of 95 per cent oxidation of the polyphenols present. As rolling in the factory is so efficient it follows that the extensive damage involved in grinding the tissue is not necessary for complete fermentation.

It has been my contention that the mechanical damage required to bring about complete oxidation of the polyphenols in the tea-leaf is sufficient to suppress the greater part of normal respiratory activity, and that carbon dioxide produced in fermentation is due to a secondary oxidation of carbohydrates with the *o*-quinones as one of the necessary H-acceptors. The most important items of evidence supporting this view are summarized below.

(1) The fall in carbon dioxide output when oxidation of polyphenols is nearly complete.

(2) The negligible oxygen uptakes and carbon dioxide outputs recorded for non-tanniferous tissue when subjected to the same degree of mechanical damage[3].

(3) The suppression of anaerobic fermentation in tea-leaf tissue sufficiently damaged to undergo complete oxidation of its polyphenols[4].

(4) The stimulation of both oxygen uptake and

carbon dioxide output when fresh polyphenol is added to completely fermented tea-leaf suspensions. This observation cannot be explained by Sreerangachar's hypothesis, but this effect is to be expected if carbohydrate oxidation depends upon the presence of *o*-quinones.

It is considered that the damage brought about either in the factory-treated leaf or in finely minced tissue is sufficient to suppress respiration almost completely, and that the carbon dioxide produced during fermentation is not a product of normal respiration.

Sreerangachar's results become completely intelligible if his mincing process is considered to produce less damage to the leaf than ours. In the Tocklai experiments an attachment used for grinding nuts to a fine paste was employed for the mincing of the leaf. This would be expected to produce a much greater extent of damage than a fine cutter, as in addition to chopping up the tissue it also gives it a considerable shear. It has been emphasized in my recent publications[5,6] that such shearing forces are to be considered as responsible for the disorganization of respiratory processes which results in tea-fermentation.

The effects of a fine chop, such as presumably was obtained in Sreerangachar's laboratory, have been studied at Tocklai. Such a mince gives a rather lower $-Q_{O_2}$, a certain amount of undamaged tissue which remains unfermented, and a comparatively high rate of anaerobic fermentation. There is therefore good reason to believe that Sreerangachar's results are due to a failure to repeat the conditions under which the Tocklai experiments were carried out. In addition it must be emphasized that Sreerangachar's views do not give an adequate explanation of the dependence of carbon dioxide output on polyphenol oxidation. The criticisms made by Sreerangachar are not therefore considered to weaken the theory of tea-fermentation advanced by the author to any appreciable extent.

Ascorbic Acid Content of Recently Harvested Cereals and Legumes

IN the course of an investigation, it had become necessary to start some guinea pig growth experiments for assay of ascorbic acid biologically. It was soon found that the animals kept on a scorbutic diet of casein, ground roasted Bengal gram (*Cicer arietinum*), ground oats, cod liver oil and salts did not cease to grow and show depletion even after three weeks. This unusual behaviour was ultimately traced to the ascorbic acid of the cereals and legumes in the diet. These grains were apparently harvested in March–April, and the experiment with the diet containing them started in May. The ascorbic acid contents of the cereals and pulses were estimated by titration with 2 : 6-dichlorophenol indophenol and are given in Table 1.

Table 1.

Material	Ascorbic acid content (mgm./gm.)
Bengal gram (ground and roasted) ..	10·31
Oatmeal (whole)	13·97
Wheat flour (whole)	5·30

Table 2.

No. of animals	Av. weight at start	Av. weight after 3 weeks	Mean growth for the period	Mean weekly growth
8	126 gm.	168 gm.	42 gm.	14 gm.

The ascorbic acid values found by titration have been substantiated by biological assay. Young growing guinea pigs were kept on the diet of casein, ground and roasted Bengal gram, oatmeal, cod liver oil and salts; when the total consumption of food by each animal corresponded to an average intake of about 1 mgm. ascorbic acid per animal per day, they showed a growth response of 14 gm. (mean growth-rate) per animal per week over a three-week test period (Table 2).

I have not seen any similar reference in the literature on the ascorbic acid content of dry cereals and legumes, so far.

High-angle Edge-flaking of Flint

SOME four years ago I carried out a number of experiments in the removal of high-angle flakes from the edges of flints, and feel that examples of the results of this work should now be made public. It will be seen, from the accompanying table, that the angles at which the flakes were removed range from 100° to 140°. The greatest length, and the greatest width, of the flakes removed are also given :

Angle of detachment of flake	Greatest length of detached flake	Greatest width of detached flake
100°	2 in.	$1\frac{4}{16}$ in.
102°	$1\frac{13}{16}$ in.	$1\frac{13}{16}$ in.
105°	$1\frac{5}{16}$ in.	$1\frac{11}{16}$ in.
110°	$1\frac{13}{16}$ in.	$1\frac{2}{16}$ in.
132°	$1\frac{7}{16}$ in.	$\frac{14}{16}$ in.
140°	$1\frac{3}{16}$ in.	$\frac{15}{16}$ in.

The detachment of these high-angle flakes from the edges of large nodules of flint was accomplished by the use of a weighty hammer-stone of quartzite. No other method of detachment was adopted. In one case the removal of a consecutive series of these flakes from the edge of a flint was accomplished. These flakes were detached at angles of 102°, 105° and 110° respectively. The angles enumerated in this note are those formed between the striking-platform and the flake-scar upon the parent block. It seems probable that further practice in this work may result in the removal of high-angle edge-flaking from flints with comparative ease and precision.

I have placed a typical series of the experimental pecimens on exhibition in Ipswich Museum.

A Nuclear Ring in the Developing Male Germ Cells of the Dog and Cat

I regard Mr. Zlotnik's[1] nuclear ring in the dog spermatid as an Aoyama picture of the same post-nuclear granules drawn in Fig. 3, plate 28 of my 1929 paper[2]. The Da Fano and Cajal pictures also differ slightly in the exact amount of silvering and in the substrate in which the silver comes to rest. As mentioned in a previous communication[3], the dog spermatogenesis is in some ways clearer to study and nterpret, and in it Mr. Collery and I have been able to follow the granules of the middle piece bead rudiment right back to the early spermatocyte. As regards the human post-nuclear body, Dr. Beams and I[4] had no silver material to study. Probably osmium tetroxide impregnates the bottom of the band first, and not the top as does silver. However, Mr. Collery has recently made me some excellent slides of human material by the Aoyama technique, and I hope to study the method of formation of the post-nuclear band in the near future. Mr. Collery and I have been unable to agree with Bell's[5] account of the origin of fat from broken-down Golgi remnants in the dog. We believe the fat appears by unmasking of droplets in the peeling-off cytoplasm. I note that Mr. Zlotnik figures the neck or middle piece bead in some of his drawings. At the present moment I believe my previous account of its origin from an argentophile structure in the spermatid to be correct; but I do not think that this structure buds off from the Golgi apparatus after acrosome formation, for the reason given above. Mr. Collery and I are still working on the origin and fate of the two argentophile beads (inner and outer) associated with the middle piece of the mammalian spermatozoon, and both of which can be found in spermatids.

I am glad that Mr. Zlotnik has been able to confirm the presence of the post-nuclear body, which I have shown to be present in the spermatozoa of various animals. There is just one point in technique which I should mention: in recent work I have noted that Mr. Collery's preparations made by the Aoyama method, cut by the freezing microtome and mounted in glycerine jelly, are superior to anything I had to study in 1929. Perhaps Mr. Zlotnik already knows the valuable papers by Popa and Marza[6] which I have found very interesting, and which are not so well known as they should be.

Science, Christianity and Truth

Two passages in the Rev. Hardwick's review of Canon Baker's "Science, Christianity and Truth"[1] call for comment.

He writes: "Canon Baker's words are only too true: 'The scientists, because they can say nothing more of man than that he is the product of evolution, here to-day and gone to-morrow, have no reply to the Nazi or Fascist or Communist assumption that liberty is only a fad or a prejudice and the individual is nothing compared with the Race or State or Working Class'."

This appears to me so extraordinary a statement, especially in the columns of Nature, that I at first thought I must have misread it. It runs counter to modern trends in evolutionary theory[2] and in sociology[3]. In point of fact, the precise opposite is probably true, namely, that evolution (under which social as well as organic evolution is, of course, to be included) provides the only external yardstick or standard by which to measure the correctness of our social principles and our ethical judgments. This has been pointed out, for example, by Waddington[4], and later in more detail by myself[5].

Secondly, the Rev. Hardwick quotes his author, apparently with full approval, as follows: "In his remarkable chapter, 'Is there a God?', Canon Baker writes: 'If there be no other ground and cause of existence than the irrational, the meaningless, the unconscious, the blind, then there is no reason to believe that our reasoning arrives at truth rather than error. . . .' Here again we have an idea which the scholastics would have grasped at once, namely, that the existence of God is pre-supposed in all our thinking, whether we realize it or not".

Whether men of science realize this or not, the great majority of them would, I imagine, agree that their criterion of "arriving at truth rather than error" lies in correspondence with fact, and is therefore provided by the scientific method of submitting their conclusions to independent verification, and refusing to accept any conclusions which are not capable of such verification, rather than in any deductions from the "ground and cause of existence" (whatever that may imply: personally I find it difficult to attach any meaning to the idea of a cause of existence).

I direct attention to these points because there is at the present time in various quarters a marked tendency to reject the scientific point of view and to revert to a pre-scientific attitude. In particular, "Science" is accused of materialism, and its relevance to social principles and to philosophical problems is called in question. Accordingly it is of some importance for men of science to think out in the fullest possible way the implications of their subject and its method, notably perhaps in fields where values are concerned, the better to resist these attempts to restrict the scope of science and its applications.

Future of Technical Colleges

IN recent educational discussions changes have been suggested in the relative status of university and technical institutions. Some of the suggestions have taken form and substance in various reports, for example that of the Institute of Physics dealing with the education and training of physicists. The policies suggested have so fundamental a bearing on the future of technical colleges of the first rank that they should be made as public as possible before any irreparably damaging step is taken. One notes, for example, that the report referred to hopes to "relieve the Technical Colleges of the necessity of preparing students for External University Degrees". The elastic term technical college includes institutions of every type from the lowest to the highest rank, and the subsequent discussion and suggestions refer to those technical colleges of the highest rank, which would suffer most greatly by this step. Such a "relief" would, in the opinion of a large number of those interested in the growth of technical education, disable and de-rank big technical institutions which have rendered sterling service to technology, and have striven hard, often with little national or local interest, to become institutes of technology of university rank and status.

Whatever policies in technical education the post-war period ushers in, the standard of highest rank technical colleges, with their fine record of service and close attention to the needs of industry, should be safeguarded more than ever in a world where technology seems destined to play an ever-increasing part. Even major technical colleges have suffered too much in the past from being maintained as subordinate institutions. From this position, the only means of escape has been to become university colleges, and in the process of transition many purely technical departments have become attached to universities, the functions of which are more normally academic. This process of accretion of technical departments to universities could not but be accelerated by the move suggested by the Committee, denying as it does the right of the technical college to give the highest training to the young technologist. The best general training which can be devised is along the lines of a university degree course in technical subjects, such as chemistry, physics, engineering, pharmacy, commerce, chemical engineering, metallurgy, textile technology and the like, and no such crippling handicap should be imposed on big technical colleges and their students as denying the former the right to their proper function, and the latter their right to the highest standard of tuition there.

In our opinion, the correct development of technical education does not lie along lines of transference of all higher flights of technology to the universities. Instead there should be in Great Britain a group of institutes of technology, properly equipped and adequately financed, of definite equality in status to the universities. Such institutions exist in the Continent of Europe and in the United States. No one there, even from the universities, would think of de-ranking them. They send out a flow of graduates who take the highest industrial posts; they contribute a steady stream of fundamental research; their professors are world-famous. The lustre of the Zurich Polytechnic, or the Massachusetts Institute of Technology, to name two of many equally splendid institutions, is as bright as that of any contemporary university. It is difficult, with the totally differe example and experience of so many other countri before one, to contemplate such a retrograde ste as that recommended by the Report, which leav the technical colleges, irrespective of their standin only minor courses of National Certificate characte and only second-rate students.

Microchemical Apparatus

The microchemical apparatus used in Great Brita before 1939 was, in the main, imported from Austri where Prof. Pregl and his co-workers instructed con petent apparatus makers such as Paul Haack, an approved for use in the exacting microchemic technique the products they manufactured.

Chemists in Great Britain have been slow to ado micro methods. We believe this to be due to number of causes. (*a*) The lack of an active organiz tion to arrange meetings and demonstrations and t develop an interest in the subject. The Microchemic Club did something towards this end, but it is no defunct[1]. (*b*) The foreign apparatus was importe and could not, therefore, be described as bein 'freely' available. The spread of a new science greatly encouraged if the apparatus for it is easy t obtain. (*c*) Arising out of (*a*) and (*b*), the diversit of views among workers and their failure to agre how microchemical apparatus should be constructe It is true that text-books describe minutely some the special points to be observed during manufacture but many features are not clearly specified, either b illustration or by literary description. Glassblowin is an art; not a precise engineering operation tolerances have to be allowed and the closer th tolerances the greater the difficulty in manufactur and hence the greater the cost.

Until, therefore, microchemists can band them selves together for their common interest and agre what they want and how it should be made, dis satisfaction with British-made apparatus will con tinue to be expressed by some of them. In the Unite States a start has been made and some approve specifications have already been published[2].

In our view the bodies in Great Britain primaril interested should appoint a panel to draw up specifi cations acceptable to both users and manufacturers These might be the British Standards Institution the Society of Public Analysts and Other Analytica Chemists, the Chemical Society, the Royal Institut of Chemistry, various Government Departments an others concerned, and work here should be linke up with what is being done in the United States.

British manufacturers are ready and willing t give their full co-operation in any project for th standardization of apparatus for this growing science This Association would welcome collaboration wit any microchemical organization in the examination from the manufacturing point of view, of any draf specifications.

MAGNESIUM-CALCIUM ANTAGONISM IN MUSCLE

y DR. G. D. GREVILLE and DR. H. LEHMANN
Runwell Hospital, nr. Wickford, Essex

IN skeletal muscle, the energy needed for the contraction is probably provided by the hydrolysis of adenosinetriphosphate. Adenosinetriphosphatase, the enzyme which catalyses this reaction, is intimately associated with myosin, the contractile protein itself[1]. There is evidence from experiments *n vitro* that elongated myosin molecules contract as the adenosinetriphosphate breaks down[2]. In the esting muscle fibre, the adenosine compounds are spatially separated from the myosin, the former being in the isotropic and the latter in the anisotropic egments; during activity the adenosine compounds migrate into the segments containing the myosin[3].

The adenosinetriphosphatase of myosin is activated by calcium ion[4,5]. Ljubimova and Pevsner[6] have eported some inhibition (*ca.* 30 per cent) by Mg++. During a study[7] of the enzymes of human tissues, however, we prepared human myosin and found that Mg++ powerfully suppresses the Ca++ activity. With very dilute rabbit myosin, where addition of Ca++ is essential, the activity in presence of 2×10^{-3} *M*.CaCl$_2$ was reduced by 82 per cent when as little as $2 \cdot 5 \times 10^{-4}$ *M*.MgCl$_2$ was present (Fig. 1).

Mg++ thus overcomes the activation of adenosinetriphosphatase by Ca++; but to determine whether this is a result of competitive inhibition, it had to be ascertained whether the inhibition by Mg++ decreases when the Ca++ concentration is raised above a value already causing maximal activation. A difficulty arose here because there is only a narrow range of Ca++ concentrations over which the activaion is maximal, since the activity falls off at higher Ca++ levels (Fig. 1). However, it was the same with 2×10^{-3} *M*.Ca++ as with 4×10^{-3} *M*., whereas the same Mg++ concentration was less inhibitory at the higher of these two Ca++ levels. This is strong evidence for a competitive inhibition of Ca++ activation by Mg++.

It occurred to us at once that this antagonism might be of significance in the so-called 'magnesium narcosis'[8], which is of clinical interest since MgSO$_4$ has been injected in combination with general and spinal anæsthetics, and is used in psychiatry to 'soften' the convulsions of metrazol therapy. The 'narcosis' consists primarily of a paralysis, of peripheral origin, of the skeletal musculature, which passes off immediately on the injection of CaCl$_2$. It is thus an outstanding example of Ca-Mg antagonism *in vivo*; but before discussing whether our observations can elucidate any *in vivo* phenomena, two possible objections must be considered.

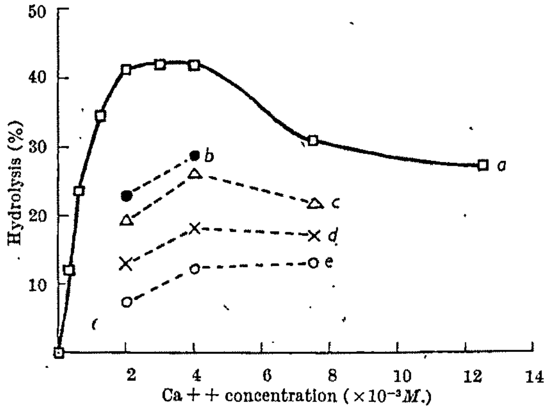

Fig. 1. Ca + + activation of rabbit myosin adenosinetriphosphatase; competitive inhibition by Mg + +. 150 sec. at 37°. 0·05*M*. glycine buffer *p*H 9·2. Per ml. reaction mixture: 0·0054 mgm. protein -N, 0·069 mgm. adenosinetriphosphate (as '7 min. P$_2$O$_5$'). Total vol. 4 ml. Concentration of MgCl$_2$ (*M*. × 10^{-5}): *a*, 0; *b*, 3; *c*, 6; *d*, 12·5; *e*, 25 (Hilger Absorptiometer used in phosphate determinations).

"Hydrolysis (%)" in Figs. 1 and 2 refers to one phosphate group, since 100% hydrolysis by myosin releases only one of the three phosphate groups of adenosinetriphosphate.

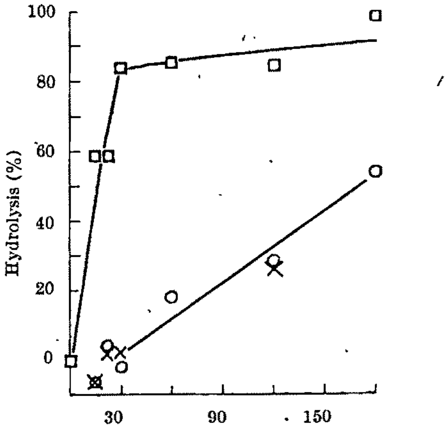

Fig. 2. High concentration of myosin, *p*H *ca.* 7; Ca + + activation and its inhibition by Mg + +. 37°. Per ml. reaction mixture: 1·2 mgm. protein -N, 0·305 mgm. adenosinetriphosphate (as '7 min. P$_2$O$_5$'). Total vol. 1 ml. ○, no addition; □, 0·01 *M*.CaCl$_2$; ×, 0·01 *M*.CaCl$_2$ + 0·01 *M*.MgCl$_2$.

First, as is usual with myosin, the above experiments were carried out at the unphysiological *p*H of 9·2. We have found, however, that Mg++ still overcomes Ca++ activation at *p*H *ca.* 7, both in presence of glycine buffer, and also (Fig. 2) when the sole buffering is provided by the myosin and adenosinetriphosphate.

Secondly, high concentrations of myosin show adenosinetriphosphatase activity in the absence of added Ca++, even with repeatedly washed protein[5]. We have found that it is much less affected by Mg++ than is the catalysis activated by *added* Ca++; as much as 0·04 *M*.MgCl$_2$ reduces it only by 35 per cent. It might therefore be objected that in muscle, where the myosin is highly concentrated, the adenosinetriphosphatase activity should be insensitive to Mg++. However, using myosin in fairly high concentrations, and measuring the activity over short time-periods (Fig. 2), we found that after thirty seconds the reaction in presence of calcium was almost complete, whereas in absence of Ca++ the conversion was negligible. Furthermore, addition of Mg++ had completely suppressed the activity induced by Ca++.

Hence if muscle twitches, which are of very short duration, fail to appear under the influence of Mg++, the enzymological evidence permits the explanation that the effect is due to inhibition of the myosin adenosinetriphosphatase. In the *frog*, this is probably the case in the later stages of the narcosis, since after injection of MgSO$_4$ into the dorsal lymph-sac the leg muscles ultimately fail to respond to direct electrical stimulation[9]. Further, when denervated frog muscle, and also single fibres, are transferred from Ringer solution to isotonic MgCl$_2$ solution, the threshold of response to electrical stimulation is raised[10].

In the *mammal*, however, present knowledge of the muscular relaxation immediately following $MgSO_4$ injection makes it unlikely that this can be ascribed to a direct action of Mg^{++} on the contractile protein, for two reasons:

(1) It is generally realized that when Mg^{++} is injected and produces muscular relaxation, it does not paralyse the muscle directly. It acts in a similar manner to curare, which interrupts transmission at the neuromuscular junction. Thus following the injection of Mg^{++} or curare, the response to direct stimulation remains when that to indirect stimulation has disappeared[11], the latter is temporarily restored after tetanization[12], and similar chronaxie relationships are observed[13].

(2) After the intravenous injection of $MgSO_4$ into dogs, the Mg^{++} most probably distributes itself through the extracellular fluid of the body[14] and is thus unlikely to come into contact with myosin.

In a paper which has just reached us, DuBois *et al.*[15] put forward as an explanation for magnesium narcosis the mechanism which we have been considering, namely, that Mg^{++} competes with Ca^{++} and prevents the breakdown of adenosinetriphosphate. This hypothesis must be rejected for the reasons given above. The increased adenosinetriphosphate content of the muscles of animals under magnesium narcosis, which is the sole evidence adduced by the American authors, might well be due to the relaxation; it remains to be shown that curare would not give the same effect.

Furthermore, the antagonism between Ca^{++} and Mg^{++} is not unique for myosin. The adenosinetriphosphatase activity of the electric organ of Torpedo[16], which is not due to myosin, is activated by Mg^{++}[17]. We have found that here Ca^{++} is inhibitory.

Electric organ extracted with 1·5 vol. of water. In each tube, 0·4 ml. extract, 1 ml. glycine buffer *p*H 8·2 (37°); 0·42 mgm. adenosinetriphosphate (as '7 min. P_2O_5'), total vol. 2·5 ml. 10 min. at 37°.

	—	*M*/250 $CaCl_2$	*M*/250 $MgCl_2$	$MgCl_2$ $+CaCl_2$
% of 7 min. P_2O_5 hydrolysed	17	6	45	7

It seems probable that this antagonism is widespread, so that when one of these ions is an activator, the other may be expected to be inhibitory. If in neuromuscular transmission some enzyme process is activated by Ca^{++}, and it is noteworthy that a dependence on the Ca^{++} level has been shown[18], Mg^{++} might be expected to suppress it. Thus for magnesium narcosis our observations may serve only as model experiments. There is, however, one phenomenon in the mammal for which they may offer a direct explanation.

Magnesium deprivation tetany in the rat is in some ways the converse of the paralysis following magnesium injection, the hyper-irritability increasing when the calcium level of the diet is raised[19]. Since the threshold of response of the leg muscles to galvanic stimulation of the motor nerve is lowered[20], and curare does not decrease the severity of the convulsions[19], it is possible that the hyper-irritability arises *in* the muscles. Although the mammalian muscle cell is probably impermeable to *injected* Mg^{++} [14], its magnesium content is high[21]. Conceivably a lowering of this level by magnesium deprivation might lead to accelerated adenosinetriphosphate breakdown by myosin, with exaggerated response to motor stimuli and the appearance of tetany.

We are grateful to Dr. R. Ström-Olsen, physician superintendent of Runwell Hospital, for his encouragement; to Drs. D. M. Needham and K. Bailey, of the Biochemical Laboratory, University of Cambridge, and Drs. G. L. Brown and F. C. MacIntos of the National Institute for Medical Research, wit whom these problems have been discussed.

RECENT ADVANCES IN IMMUNOCHEMISTRY*

By Dr. W. T. J. MORGAN
Lister Institute of Preventive Medicine

ALTHOUGH methods for protecting man an animals against certain infectious diseases hav been known for many years, it is only within the la decade that the nature of the substances that indu this resistance have been at all clearly defined an their composition and structure expressed in terms the fundamental sciences, chemistry and physics.

At first it was believed that the strict specifici of bacterial antigens—the substances inducing t formation of the immune bodies that protect again infection with the homologous micro-organism depended largely on the chemical and physical diffe ences that existed between the bacterial proteins the different kinds of organisms. This view w abandoned when it was shown that filtrates fro virulent bacterial cultures contained a soluble specif polysaccharide substance and appeared to be fr from intact protein. The specific polysaccharid which were found to be responsible for the chara teristic specificity of each organism were, howeve shown to be devoid of antigenicity, or at most show this property only weakly. The results of the researches on the specific polysaccharide componen of the whole bacterial antigen were of the greate importance because later studies, which developed a direct result of this work, formed the basis of o present knowledge of antigenic structure.

---

* Substance of a lecture before the London and South Easte Counties Section of the Royal Institute of Chemistry on June 1

Until quite recently no attempt to separate the somatic antigens from the bacterial cell had been successful, but within the last ten years several methods for the isolation of fully active bacterial antigens from Gram negative organisms have been elaborated. The earliest practical method to accomplish this was introduced by Boivin, who extracted bacteria at 0° with $0 \cdot 2$ *N.* trichloracetic acid (*p*H $1 \cdot 0$–$2 \cdot 0$). The extract was apparently free from intact protein and was powerfully antigenic. At about the same time and quite independently, Raistrick and Topley found that by the action of trypsin on certain bacteria it was possible to bring the antigenic complex into solution. The digestion was carried out at *p*H $8 \cdot 2$–$8 \cdot 5$ for several days at 37°. Methods of isolation that depend on extraction of the bacteria with cold anhydrous organic solvents, such as diethyleneglycol, in which native proteins and many bacterial somatic substances are insoluble, have also been successfully employed to isolate these important biological complexes.

It is certain that as our knowledge of the nature of the bacterial somatic antigens grows, we shall find very different types of chemical structures associated with bacterial and tissue antigenic complexes. We already know, however, that certain groups of bacteria possess antigens that are built up from similar types of molecules arranged together as polymolecular aggregates. As an example of this similarity in structure the *O* somatic antigens of *Bact. typhosum* and *Bact. dysenteriæ* (Shiga) may be mentioned. Each antigen is built up of a polysaccharide, specific for the organism and responsible for its characteristic serological reactions, and a polypeptide-like component (most probably a conjugated protein). Other components of the native antigenic complex, such as phospholipin, also occur, and it is possible that further unidentified substances are present.

In certain instances, however, it has been shown that of all the components present in the native antigenic complex only two, the polysaccharide and protein, are essential for the manifestation of antigenicity. It seems probable, therefore, that a bacterial antigen as it exists in the intact bacterial cell is not a simple compound of rigid chemical composition, but consists of a labile molecular aggregate possessing an essential component—such as a polysaccharide—of definite chemical structure and of fixed composition, which determines the strict specificity of the antigen, together with other loosely bound constituents which endow the essential component with antigenic properties. Only part of these physically associated molecules are necessary for the manifestation of the specific antigenic properties, and certain of these constituents can be dissociated from the labile complex during the isolation and purification of the antigen without producing more than a moderate reduction in the antigenic capacity of the active material. More thorough physical disaggregation of the polymolecular complex into single types of molecules will lead to complete loss of the original antigenicity that gives rise to the homologous immune body.

Considerable support for this conception of antigenic structure was obtained when it was observed that the isolated and undegraded specific polysaccharide component of the antigen could be re-combined with the conjugated protein component, under almost physiological conditions, to form an antigenic complex that would give rise to antibodies specific for the polysaccharide component of the newly formed complex. Neither component showed any specific antigenic properties when tested alone. Furthermore, it has been found that the non-antigenic, specific polysaccharide of one organism will form an antigenic complex when combined with the conjugated protein component derived from the corresponding somatic antigen of another organism that belongs to an entirely different bacterial species. The nature of the bonds that hold the different types of molecules together as a polymolecular aggregate is unknown. Future work will certainly decide whether the association of the various component molecules is due to 'salt-like linkages', hydrogen bonds, van der Waals' forces or to some as yet unknown mechanism. It can only be stated at the present time that the forces concerned give rise to an aggregate with sufficient stability to make it behave as an independent molecular species.

Further evidence in support of these ideas on antigenic structure is derived from the success with which certain non-antigenic polysaccharides of both vegetable and animal origin have been converted to full antigens by combination with the reactive bacterial conjugated protein mentioned above. The artificial antigens again give rise to immune body that reacts specifically with the polysaccharide component used to build the antigenic complex.

Antibodies against the polysaccharides agar-agar, cherry gum and gum acacia have been described, and more recently immune sera capable of specifically agglutinating human *A* red blood cells but not those of groups *B* and *O* have been prepared by combining a naturally occurring but non-antigenic polysaccharide complex that possesses blood group *A* specificity with a bacterial somatic conjugated protein. It is believed that these powerful anti-*A* sera will be useful in certain blood-group determinations and will prove to be of value in the technique of differential agglutination.

It is clear that bacterial and tissue antigens that are largely polysaccharide in nature belong to a class of substances that are characterized as 'large molecules'. They display unusual properties and it will be necessary to develop new methods for handling them and new chemical conceptions to explain their nature and function.

RADIO RESEARCH ON METRE WAVES

THREE papers by members of the staff of the Radio Department of the National Physical Laboratory appear in the March issue of the *Proceedings of the Wireless Section of the Institution of Electrical Engineers.*

The first paper, on a study of the propagation of ultra-short waves between Guernsey and England, by Dr. R. L. Smith-Rose and Miss A. C. Stickland, was referred to in NATURE of January 2, p. 31.

Following this is a paper by Messrs. F. M. Colebrook and A. C. Gordon-Smith, entitled "The Design of Ultra-Short Wave Field-Strength Measuring Equipment". This comprises a description of the essential features of design and construction of apparatus for measuring field-strength, and suitable for any radio-frequencies between 30 and 600 megacycles per second; that is, wave-lengths between 10 and $0 \cdot 5$ metres. The equipment is of a relatively narrow band width type (about 20 kc./s.), and is primarily intended for the measurement of continuous-wave fields of the order of tens or hundreds of microvolts per metre. The description is supplementary to a previous paper on the subject which dealt with measurements at wave-lengths down to about 7 metres. For shorter wave-lengths than this, a half-wave-length dipole is the most practicable form of aerial, and this is coupled to the frequency-change unit by a flexible transmission line. For wave-lengths less than about one metre, it is an advantage, from the viewpoint of ease of operation and increase in sensitivity, to use a flat sheet reflector behind the aerial, together with a shorter transmission line. The frequency change unit incorporates a diode, and it is convenient to operate the local oscillator at one half or one third of the signal frequency.

The measurements made with this equipment rest ultimately upon the intermediate-frequency amplifier, which can be calibrated for gain over a wide range. Such calibrated amplifiers have been developed at the National Physical Laboratory, and used extensively for field work: an improved version has been developed for laboratory work, and the more important features of this have been incorporated in a commercial form of the field equipment. In operation at the higher frequencies, it has been found necessary that the complete assembly should be thoroughly screened: the batteries are contained in a separate metal box and connected to the amplifier and frequency-change units by screened flexible leads and screened plugs. The overall calibration of the complete equipment is carried out by the measurement of a known, preferably horizontally polarized, field produced by a radiation method described in a previous publication.

The third paper in the series is by Dr. J. S. McPetrie and J. A. Saxton, and is entitled "The Determination of the Electrical Properties of Soil at a Wave-length of 5 Metres (Frequency 60 Mc./s.)". This gives an account of experiments made to determine the electrical properties of various ground surfaces from the reflexion coefficient obtained for radiation at normal incidence. The experimental technique used a horizontal transmitting aerial set at a height of about 12 m. above the ground; and the stationary wave pattern formed between this aerial and the ground was explored by observing the current induced in a horizontal receiving dipole placed at various heights. The observed results showed good agreement with theoretical curves calculated on the assumption that reflexion takes place actually at the ground surface. The sites investigated varied from wet clay to gravel; the corresponding values of dielectric constant ranged from about 5 to 60, while the values of conductivity varied from less than 10^8 up to, but not greater than, 10^9 E.S.U.

The lowest values in each case refer to a site which had been excavated to a depth of seven feet, exposing a surface of pure gravel, with no sign of humus or decayed vegetation. A nearby undisturbed site on the same subsoil, but with about nine inches of grass-covered soil on top, gave a reflexion coefficient similar to that obtained on other grass-covered sites. The above values of the electrical constants obtained with undisturbed soil agree with those measured in the laboratory for samples of similar types of soil. The experiments were made during winter months under rather wet conditions: the values of both dielectric constant and conductivity would probably be less during the summer.

FORTHCOMING EVENTS

Friday, July 16—Monday, July 19

Association of University Professors and Lecturers of th Allied Countries in Great Britain (at New College, Oxford).

Saturday, July 17

At 9.45 a.m.—Separate Meetings of Sections.

At 2.30 p.m.—Collective Groups of Meetings.

Sunday, July 18

At 10 a.m.—General Meeting.

Monday, July 19

At 10 a.m.—International University Conference of the Associatio of University Teachers.

Wednesday, July 21

Institute of Fuel (in the James Watt Memorial Institute, Grea Charles Street, Birmingham), at 2.30 p.m.—Mr. L. W. Andrew an Dr. E. A. C. Chamberlain: "Radiant Heat for Industrial Processes—'Infra-red' by Gas".

Friday, July 23

Royal Aeronautical Society (at the Institution of Mechanica Engineers, Storey's Gate, Westminster, London, S.W.1), at 5.30 p.m —"The Education and Training of Aeronautical Engineers".

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Speech Therapist (full-time)—The School Medical Officer, Town Hall, Ealing, London, W.5 (July 22).

Responsible Teacher of Engineering in the Batley Technica College and School of Art—The Director of Education, Educatio Offices, Batley, Yorks. (July 22).

A post on the Chemical Research Staff of the Tin Research Institute—The Secretary, Tin Research Institute, Fraser Road Greenford, Middx. (July 24).

Combined post of full-time (acting) Radiotherapist to the Liverpool Cancer Control Organization and (acting) Medical Director of the Radiotherapeutic Department of the Liverpool Radium Institute—The Hon. Secretary, Liverpool Cancer Control Organization, 66 Rodney Street, Liverpool 1 (July 24).

Headmaster of the Day School attached to the South-West Essex Technical College and School of Art, Walthamstow—The Chief Education Officer, County Offices, Chelmsford (July 24).

Women Psychiatric Social Workers at the Birmingham Child Guidance Clinic—The Chief Education Officer, Education Office, Margaret Street, Birmingham 5 (endorsed 'Psychiatric Social Worker') (July 29).

General Manager and Engineer of the Sheffield Water Undertaking—The Town Clerk, Town Hall, Sheffield 1 (July 31).

Speech Therapist (full-time)—The Secretary for Education, Education Offices, York (August 6).

Chemist and Assayer on the establishment of the South African Mint, Pretoria—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, London, W.C.2 (August 31).

Heads of the Departments of Physiology, Medicine, and Surgery—The Bursar, Royal Veterinary College and Hospital, at The University, Reading (October 1).

Chair of Naval Architecture—The Acting Secretary of University Court, The University, Glasgow (October 4).

Science and Mathematics Master at the English High School for Boys, Istanbul—The British Council, 3 Hanover Street, London, W.1 (endorsed 'Istanbul').

Analyst and Animal Nutrition Assistant (temporary)—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

Psychiatric Social Worker—The Medical Superintendent, Springfield Mental Hospital, Tooting, London, S.W.17.

Teacher of Mathematics and Science in the Junior Technical School (temporary)—The Clerk to the Governors, North-East Essex Technical College and School of Art, Colchester.

Assistant Engineer for the Government of Northern Rhodesia Public Works Department—Ministry of Labour and National Service, Central (Technical and Scientific) Register (Reference E.697), Alexandra House, Kingsway, London, W.C.2.

Engineer (Mechanical) to carry out work of national importance—The Ministry of Labour and National Service, Central (Technical and Scientific) Register (Reference No. C.1660), Alexandra House, Kingsway, London, W.C.2.

Industrial Planning Officers (9) (Reference No. C.1771), and Assistant Industrial Planning Officers (6) (Reference No. C.1772), for the Aeronautical Division of the Department of Supply of the Government of India—The Ministry of Labour and National Service, Central (Technical and Scientific) Register (quoting appropriate Reference No.), Alexandra House, Kingsway, London, W.C.2.

LEADERSHIP IN A DYNAMIC SOCIETY

THERE is a striking parallelism of thought between the address on "Science and its Changing Social Environment" which Prof. P. W. Bridgman, of Harvard University, delivered to the American Physical Society on January 23, and that of Mr. Herbert Morrison to the Yorkshire Regional Council of the Labour Party at Leeds on April 3.

Prof. Bridgman's opening remarks on the relations of science and society, with his insistence that men of science should not acquiesce too readily in the implication of social responsibility for their discoveries, because society is the servant of science even more, and in a more fundamental sense, than is science the servant of society, are a challenge to lucid thinking in a field where terms are by no means clearly defined or precisely used. Even more fundamentally he directs attention to a danger referred to by Mr. Morrison, of which many scientific workers appear as yet to be unconscious.

In the long run, it is true that society is a better place for everyone when there is intellectual freedom and encouragement and flourishing activity in pure science. Prof. Bridgman urges that now is the time to insist more than ever that society must conform to the pattern of service to science. He suggests that changes now taking place are worsening the position of those who think as compared with those who do not. Social institutions are changing rapidly, and if society is to become a place where intellectual activity is encouraged and intellectual ability prized, those who think must fight for it. If they do not, we cannot assume that society will evolve so that the individual will be allowed to engage in independent intellectual activity.

Prof. Bridgman enters a sturdy defence of the old American conception of democracy as equal opportunity for ability to rise to its natural level, and he challenges outright a social philosophy that attempts to set any upper limit to the value of the contribution which a man of unusual ability can make to his society, particularly in time of war. Our conviction, he says, has not been strong enough that a society is a good society in which intellectual ability is prized and rewarded. We are passively accepting a change in the economic system by which the relative position of all intellectual workers, including the scientific worker, is being debased and in which assurance and commitments made by society in the past are being needlessly scrapped.

In facing this situation, our primary task, Prof. Bridgman urges, is one of education. We must make and seize our opportunity to proclaim our conviction that a society in the long run is the best society where those who have the ability are given every opportunity and inducement to practise the pursuit of truth and of understanding. We must teach our youth a social philosophy which recognizes that society is a means and not an end, and we must give them a technique by which they can discover those ends which they can accept with intellectual integrity as making society worth while.

Prof. Bridgman's views will no doubt meet with some criticism, but there are many scientific workers in Great Britain who will welcome this outspoken appeal for clear thinking. At least we owe it to our American comrades in arms to understand the trend of their thought in this question of international as well as national import. The reflexion of so much of its thought in Mr. Morrison's speech is the more suggestive for this very reason.

Mr. Morrison's address was concerned primarily with the relations between the State and industry in their threefold aspect of full employment, productive efficiency, and wide and fair distribution of the products of industry. The picture he drew of some of the effects of monopoly in a substantial fraction of British industry in the period between the Wars, with the decline of real enterprise, of thinking, planning and invention, and a decline in boldness and the spirit of adventure, is no fanciful picture but a sober warning. It is uncomfortably reflected even to-day, for example, in far too many utterances of the commercial interests to be disregarded.

"A case can be made for private enterprise," said Mr. Morrison, "in appropriate fields There is a very powerful case for public enterprise. There is no case whatever for private unenterprise, for private ownership and control without the spur either of a free market and free competition or of real social purpose. . . . An industry which makes security its sole aim is a menace. Unless private enterprise is prepared to take the risks which are its historic function, private enterprise has no function."

That was well said, and the warning was needed if only as a spur to the fundamental thinking about the relations of State and industry, and the balance between public and private enterprise, that are required if we are to evolve the new social technique or control without which planning may lead us into fascism and totalitarianism. Mr. Morrison spoke wisely also about this very question of control, which he visualized not as restrictive but, given the right methods and the right men, as constructive and stimulating. The dangers of restriction have been clearly emphasized in such studies as Dr. Hermann Levy's "Retail Trade Associations", and it is a main purpose of Prof. W. H. Hutt's "Plan for Reconstruction"* to deal with and overcome these dangers.

In the new controls to be developed, Mr. Morrison discerns four elements: expert knowledge of the industry, labour, expert knowledge of the needs and interests of the consumers, and the State. The essential problem is to devise the appropriate means by which these interests and elements can function harmoniously. The State, Mr. Morrison considers, should be represented by officers specially trained to understand and work with industry, whose duty is to watch the interest of the community as a whole. If they have a bias, they should be consumer-minded rather than producer-minded, in order to ensure efficient public-spirited control. Efficiency auditing rather than price control is what is required, and cost accounting should develop into a professio which should be the watch-dog of public interest.

Guided and informed in this way, Mr. Morriso believes that our monopolies could be made to serv the public need and to promote an expanding an not a restrictionist economy. An industry whic consciously pursues social ends can be invigorate thereby as much as by the spur of competition an the free market. He visualizes a place for publi ownership where appropriate, and a place for privat enterprise also with public control, and resting upo and supporting national policies of social and industrial welfare.

This challenge to closer and more constructiv thinking about the relations of State and industry with its warning about the danger of a policy o restrictionism, finds its reflexion not only in Prof Bridgman's address but also in other quarters in th United States. Much the same ideas, for example have been expressed in the American periodica *Fortune* in different terms. Here reliance appears t be placed on the enforcement of the anti-trust laws but the danger of restrictionism is recognized a clearly as by Mr. Morrison, and the objective i essentially the same: an economy in which freedom of enterprise is preserved side by side with the socia control essential to secure certain minimum standards

The point is that freedom of enterprise mean enterprise and expansion, not restrictionism, with al that is inherent in the idea of adventure and willingness to accept risk. Without that spirit, neither i science nor elsewhere can we make the advances i thought and in technique that are essential if a new world order is to realize the hopes that the present struggle has stimulated. It is not enough just to think of the opportunities which the general loosening u of our social structure under the impact of total wa undoubtedly gives us. These opportunities must b approached in the right spirit, seized and explored by creative and fertile minds, alive to the issues involved and willing to examine them and to turn them not to personal advantage only but also to the benefit of mankind.

The great danger is in fact what Prof. Hutt refers to as the frozen imagination of statesmen and officialdom, which refuses to recognize that the present economic arrangements and the ideas on which they are based are antiquated and obsolete, leading to inequality, a substratum of poverty, and insecurity. Under the cloak of a spurious superficial orderliness, due to imposed uniformity and rigidity, our productive arrangements have become increasingly chaotic and unco-ordinated. Productive power has been withheld or exterminated in the interests of the private incomes of sets of capitalists and workers, while technical developments which cause capital values to fall are usually regarded as a threat to prosperity.

Prof. Hutt argues cogently that security, peace and prosperity all depend on the creation of a new order from which the right to restrict production has been banished, and this belief is the foundation of the plan for reconstruction which he outlines in detail in his book. He would reserve for the State only those basic functions with which the very human and fallible men who form governments can be entrusted, but the planned system for directing the use, under continuously tested foresight, of all the resources in the community, would give our democratic institutions an organized transition away from the authoritarian and monopolistic influences which have been frustrating the forces of order and co-operation.

---

* Plan for Reconstruction: a Project for Victory in War and Peace. By Prof. W. W. Hutt. (International Library of Sociology and Social Reconstruction.) Pp. viii+328. (London: Kegan Paul and Co., Ltd., 1943). 18s. net.

This plea for both freedoms—freedom to work and plan for the full use of the resources of the community in an expanding economy—is one that is not always easy to follow in its details, but as an attempt to invent or develop new institutions appropriate to the needs of to-day it merits careful consideration. As such, however, it challenges many preconceived ideas, among them the functions and organization of professional workers, and the chapter on professional security is one that claims serious attention from scientific workers. Dealing specifically with the medical profession by way of illustration, the principles Prof. Hutt outlines are intended to be applied in the organization of any profession.

There can be no question that professional organization, however sincerely conceived as an attempt to maintain high standards of professional qualification and practice in the public interest, tends, especially in a legally 'closed' profession, to become unduly conservative both towards advances in professional technique and practice, and towards entry into the profession, as well as unconsciously to place the security and interests of the profession before that of the community in general. This is a natural and possibly inevitable tendency, and Prof. Hutt's proposals represent an attempt to reconcile the interests of a profession and those of the public. He suggests a system of independent control which, while protecting established income rights, would prevent professional organization standing in the way of equality of opportunity and efficient services, opening the entrance to the professions so that the availability of family income to pay for training does not act as a major selective factor.

In what he says of the organization of the medical profession, Prof. Hutt has entered boldly on controversial ground, but the issues he raises must be frankly faced in the discussions now proceeding on the establishment of a State Medical Service; and the more general questions cannot be evaded by scientific workers who are concerned to make their full contribution in the task of post-war reconstruction. Like Prof. Bridgman and Mr. Herbert Morrison, he should stimulate some fruitful and fundamental thinking about the relations of society and science, the mechanics of living in an ordered but progressive society, developing new techniques of social control to serve its changing and growing needs. The clash between freedom and control, individualism and co-operation, the deep paradox and conflict of feelings in the lives of men which is reflected in the institutions they set up to serve their purposes, is given fairly enough, though perhaps not quite so clearly as by C. I. Barnard, whose study of the functions of the executive has a relevance here which deserves attention.

The belief in the power of the co-operation of men of free will to make men free to co-operate; that only as they choose to work together can they achieve the fullness of personal development; that only as each accepts a responsibility for choice can they enter into that communion of men from which arise the higher purposes of individual and of co-operative behaviour—these beliefs, like Barnard's further belief that the expansion of co-operation and the development of the individual are in mutually dependent realities, and that a due proportion or balance between them is a necessary condition of human welfare, are inherent in the views of Profs. Hutt and Bridgman and of Mr. Morrison. It may well be that in his keen analysis of co-operative systems and the structure and functions of organizations in such systems, Mr. Barnard has given us valuable clues for the evolution of the new forms of organization required to serve our new purposes, and for the failure of the old. Certain it is that we must heed his warnings concerning the disregard of informal organization, the recognition of the physical, biological and social factors in co-operation and the confusion of morality with responsibility. The strategic factor in co-operation generally, he reminds us, is leadership. In the dynamic expression of leadership it is moral creativeness, preceding, but depending upon, technical proficiency and the development of the appropriate techniques.

THE AMARAVATI SCULPTURES

Amaravati Sculptures in the Madras Government Museum

By C. Sivaramamurti. (Bulletin of the Madras Government Museum, New Series—General Section, Vol. 4.) Pp. xviii+376+45 plates. (Madras: Government Press, 1942.) 14.8 rupees.

THIS work is essentially a description of those sculptures and inscriptions of the Amaravati Stupa which are now preserved in the Madras Museum. There are also important slabs in the British Museum; and if they seem there to be as much out of place as the Elgin Marbles, some excuse may be found in the story of their discovery and the dissolution of the monument. It was discovered in 1797 by Colonel Colin Mackenzie of the Trigonometrical Survey at Amaravati, a town on the south bank of the Krishna some sixty miles from the mouth. A local landowner was found to be removing the materials for the establishing of a new town. The Muslims were also removing marbles for their mosques, and they appear to have taken care to efface all signs of idolatry from the slabs.

The story of its subsequent disintegration is not a cheerful one. Nothing of the original stupa now remains, but a good idea of the form of the structure can be gained from the stupas represented on the carvings. The Buddhist stupa, a development of the tumulus, consists, in its Indian form, of a solid hemispherical stone body raised on a low cylinder (in this case about the height of a man) and surmounted by a square structure called the *harmikā*. In the centre were preserved the relics, either bodily remains or other objects of devotion. At Amaravati the whole was surrounded by a carved railing with four gateways, and it was chiefly this railing and the corresponding cylindrical portion of the stupa that contained so many of the carvings, scenes from the life of Buddha or from his lives in previous incarnations, as well as designs of free artistic invention.

The stupa was described in a monograph by James Burgess in 1887, but Dr. C. Sivaramamurti, curator of the Archæological Section, Madras Museum, has now been able to do the work more completely, and especially to discuss the inscriptions in detail. He makes four sculptural periods extending from 200 B.C. to A.D. 250. The sculptures are discussed from two points of view. He first analyses the details of the scenes, the gods, animals, articles of dress and furniture, ornaments, arms, etc. This is the most original part of his work, and his own beautifully executed drawings in plates I–XIII increase its importance. There is no doubt that Western scholars have often been unable to recognize the nature of the objects in Indian designs, and this is the kind of thing that only an Indian can properly undertake. The author's knowledge seems to be much more at home in Hindu literature than in Buddhistic, and it can scarcely be expected that he has always said the last word.

In the second place, he undertakes to identify the scenes portrayed in the carvings with the events as recounted in the Buddhist legends. The two main divisions of Buddhism after the second Council, he tells us, were Thera and Mahasanghika. The school of the Theras is that now represented by the Pali Buddhism of Ceylon, and certainly with that we have nothing to do. He appears to identify the schools found at Amaravati with branches of the Mahasanghika, and yet although we have a large collection of legends in a well-known Mahasanghika work, the *Mahāvastu*, he never once appeals to it, nor does he ever directly quote the *Lalita-vistara*, another rich collection of legends. The result is that, by depending on the Pali documents, he has misinterpreted some of the scenes and failed to recognize others. Even his references to the Pali are only to translations, so that he is quite at the mercy of the whims or errors of the translators. That is the reason why he absurdly introduces angels and archangels into Buddhist mythology—merely because one erratic translator objected to speaking of gods or devas. Sometimes he sees the difficulties in which he is landed, as in the miracle of the Rose-apple Tree. The story is that once while Buddha meditated under the tree the shadow of the tree stayed still. According to the Pali, this took place when he was an infant. But in the sculptural scene he is a young man, and that is how he is described in more than one Sanskrit account. Yet the author, although he sees that the Pali version does not fit, proceeds to give it, and finally quotes Kshemendra, a Mahayanist poet who lived some centuries later than the date assigned to the sculpture. So, too, in the story of Sujātā. She was a girl who offered food to Buddha just before his enlightenment. But in the sculptured scene (which is mutilated) there are at least six girls, and the author speaks of "attendants". But in the Pali account, which he follows, the only attendant is a slave girl. Here, too, he has missed the real legend, in which Sujātā is the last of a troop of ten village girls.

The inscriptions, numbering a hundred and twenty-six, are mostly in a Middle Indian dialect, and have evidently been very carefully examined with due reference to earlier decipherers. They are chiefly dedicatory formulæ of a few words, such as, "Pious gift of the lay woman Sivalā with her sons and daughters". Many of them record the gift of a pillar, a slab, or a cross-bar. They are interesting in throwing light on the kind of people who contributed to the building of the structure—laymen and lay women, monks and nuns, merchants, bankers, and whole townships. Much the longest inscription is one of forty-seven lines in Sanskrit, giving the genealogy of a dynasty of Pallava kings. It is imperfect at the end, and the dedication, if any, has disappeared. It is remarkable that the author, who has much to say about other dynasties of South India, here makes no comment, and even ignores the description of Burgess. Some explanation of this silence appears to be wanted.

Indian authors are very much at the mercy of the Indian printer, so that in the matter of exact recording not all blame can be attributed to the author. Nevertheless, the result in the present case is unfortunate, and scholars are not likely to be satisfied without seeing the originals or rubbings of them. The single plate containing photographs of the rubbings of seventeen inscriptions does not carry one very far.

The author has collected much historical information about the Andhras, who occupied much of the Deccan during the most flourishing period of the stupa. He also gives what passes as the history of the earlier period of Buddhism according to the Pali tradition, but these matters do not throw light on the history of the stupa, and as his views rest on secondary sources, discussion of them at present would be fruitless. The same may be said about his theories of the origin of the Buddha image and Buddhist symbolism. These are still matters of controversy, as he admits, and at present more warmth than light prevails. He is to be commended on his sober attitude, and on avoiding so far as possible disputes which in the present state of feeling are not likely to receive a final answer.

E. J. Thomas.

COMPARATIVE VERTEBRATE ANATOMY

Comparative Vertebrate Anatomy

By Libbie Henrietta Hyman. Second edition. Pp. xx+544. (Chicago: University of Chicago Press; London: Cambridge University Press, 1942.) 3.50 dollars.

Those who teach zoology and know the labour of abstracting the works of living comparative anatomists in an effort to amend the mistakes and imperfections of current text-books will find in Miss Hyman's book an accurate presentation of modern facts and views. Since Wiedersheim and Kingsley wrote their text-books on comparative anatomy, so much has been added to knowledge that our generation can no longer accept wholly their evidence or their opinions. What Miss Hyman has attempted is a comprehensive study of *research treatises* in order that she can dispense with dogmatic assertions and present the subject as a living, moving science, "to give the student a picture of a vast field full of controversial issues and unsolved problems, depending for their solution on future painstaking embryological and anatomical researches". We are wholeheartedly in sympathy with her aims, and congratulate her on the success that has crowned her efforts. She has demonstrated to the zoological world that despite present trends and fashions, morphology is not 'played out', as some would have us believe, but is still the foundation of zoology, which the physiologist, the experimentalist and all other sub-sections of the science cannot ignore.

The book is the second edition of a twenty-year-old "Laboratory Manual for Comparative Vetebrate Anatomy", and combines theory and practical work, but always with the intention that the dissection should illustrate and assist in the interpretation of the text. Although the comparative method is followed in dealing with organs and systems, it is realized that the animal as a whole must be studied, and the first five chapters are devoted to the anatomy and development of types. The remaining nine chapters deal with the skin and exoskeleton, the endoskeleton, the muscular system, the cœlom, the digestive, respiratory, circulatory, urogenital and nervous systems. A comparative study of the cœlom is welcome, and also the section on that most neglected subject, the muscles. Each system is traced from its embryonic beginnings through its changes in the vertebrate groups to the mammals. Practical directions, written up from actual dissections, are given, chiefly from the dogfish, skate, Necturus, turtle, pigeon, cat and rabbit. All technical words are defined when first used. Each chapter is provided with a summary and a list of references for further reading. An appendix lists technical terms, giving their origin and pronunciation. There is also a section dealing with the killing, preparation, injection and preservation of the material.

The illustrations are clear, simple and mainly schematic, and no detailed figures of dissections are given, as the author wishes the student to examine the specimens for himself. Labelling by using the full name of the parts delineated is a great improvement on the old method of using letters or abbreviations. On the whole, the number of illustrations is somewhat meagre and their quality disappointing. This is particularly so in the section dealing with the endoskeleton. From the land of W. K. Gregory we expect more interesting text and diagrams than are here presented. Even so, the author apologizes for treating "the skeleton . . . at greater length than is commonly the case", and she realizes "the importance of this system in the study of phylogenetic and evolutionary questions". A few good diagrams, for example, illustrating the anapsid, diapsid and synapsid conditions in reptiles and their modifications in mammals, the evolution of the complete hyobranchial apparatus, or of the changes in the carpus and tarsus in different groups, would be helpful.

In her choice of animals to illustrate evolutionary sequences the author is guided by the customs of American universities, but the British reader will be surprised to find Balanoglossus relegated to the Invertebrates, and very little mention made of the Osteicthyes, except for the ganoid fishes. On the other hand, Latimeria and Polypterus are in their proper setting, and the orders of mammals have been expanded in consonance with modern views of their relationships. Due regard is given to the divergent opinions of specialists, and the sections are logically presented. Very few criticisms of the subject matter are necessary, but *branches* of the precaval and postcaval veins, homologous *to*, and *plexi* are unfortunate in an otherwise scholarly work. Also is not *transverse bone* a more convenient name for a bone that is sometimes ectopterygoid and sometimes transpalatine ?

The book ends abruptly after the chapter on the nervous system. A chapter correlating the evolutionary history of the various systems is needed, since each system has become what it is to-day in virtue of its relation to other parts of the body. The evolution of the jaws, for example, is dependent on the evolution of the facial musculature, and on the modifications in tooth structure from homodont grippers to heterodont masticators. Or again, the vogue for size, complexity and multiplication of bony parts, which reaches its maximum in the reptiles, is followed by the welding together of loose units and the simplification and diminution in their number in the mammals. The purely comparative method has its dangers, because the student loses touch with the animal as a whole, and so fails to comprehend correlated trends in evolution.

The book is well printed and produced by the University of Chicago Press.

GENERAL ASTRONOMY IN SPANISH

El Firmamento

Por el Rev. Luis Rodés. Pp. xi+689. Segunda edición. (Barcelona and Buenos Aires: Salvat Editores, S.A., 1939.)

THE first edition of this standard Spanish textbook was published in 1927. It has now been brought up to date (1939), mainly by a considerable expansion of the sections on the external galaxies. No mention is made in the text of such recently discovered objects as Hermes or Jupiter X and XI, or (specifically) of the geophysical effects of chromospheric eruptions, but Pluto has a short section to itself.

The treatment followed in the first edition is preserved : the text contains a minimum of mathematics and a maximum of illustrations. These latter are on a scale which is unfamiliar to British eyes accustomed to war-time publishing standards ; in addition to the numerous explanatory diagrams, there are literally hundreds of magnificent plates, scores of them of full-page size, in half-tone, photogravure and colour. Perhaps the most striking feature, unusual in a book of this sort, is the section on the earth. This takes 150 pages to deal with its subject, and does it so thoroughly as almost to merit description as a popular treatise on climatology and meteorology in its own right. Striking parallels are drawn between the solar and terrestrial atmosphere by contrasting photographs of chromospheric prominences with pictures of terrestrial smoke, cloud and wave formations.

The author wisely makes no attempt to discuss the more advanced branches of the subject, where a mathematical approach can scarcely be avoided. The matters with which he does deal are treated authoritatively. The reviewer has noticed only minor slips, such as, for example, those on p. 147, where references to "Prof. Chapmann" and "Prof. Lindeman" testify, no doubt, to the difficulties of the Spanish compositor. The book may be recommended as an excellent popular account of astronomy. British readers who do not know Spanish but have a working acquaintance with French and an elementary grounding in astronomy should find no difficulty with the text, while the illustrations can be appreciated by anyone who has eyes to see.

Optics

The Technique of Definition. By Arthur Cox. Pp. 331. (London and New York: The Focal Press, Ltd., 1943.) 15*s*.

THE Focal Press is to be congratulated in having secured Mr. Cox as the author of this volume on camera lenses and allied optical equipment. The book gives a non-mathematical account of lens defects and describes the various lens combinations employed in photographic objectives to improve the definition and increase the aperture. Very useful information about the focus, angular field, aperture and type of lens has been tabulated and illustrated for a wide range of lenses produced by many different firms.

Several tables giving figures for depth of focus are included, but perhaps overmuch attention is given to this in view of its dependence on the nature of the subject being photographed and the extent to which the lens is corrected. There are also sections on methods of testing, the use of polarizing screens, colour filters and infra-red filters, and reference is also made to the reduction of reflexions at glass-air surfaces by the deposition of thin films on the surfaces.

Photographers should find the book of considerable value, enhanced as it is by many diagrams of an instructive and original character. The weakest part is the title. The book is neither a treatise on optics nor one on the technique of definition, but is a book on photographic optics; it is described as such, oddly enough, on the dust cover, but not in the book itself. However, it is the contents that matter, not the title. W. D. W.

An Introduction to Organic Chemistry

By Dr. J. W. Baker. (Dent's Modern Science Series.) Pp. vii+177. (London: J. M. Dent and Sons, Ltd., 1941.) 3*s*.

THE book provides an admirable general introduction to the subject and will commend itself both to student and teacher for its simplicity of approach. The latter is achieved by concentrating attention on the structure, reactions and inter-relationships of the more important groups which continually recur in organic compounds by a study of the simplest members containing them. This restriction of scope undoubtedly has great advantages, but it inevitably deprives organic chemistry of what is, to many students, one of its most attractive features, its association with naturally occurring compounds of biological significance. Excellent detailed accounts of some fifty-six experiments, illustrated with clear line drawings, are included at the end of each chapter.

Theoretical Organic Chemistry

By Dr. J. B. Cohen. Revised edition by Dr. P. C. Austin. Pp. xv+622. (London: Macmillan and Co., Ltd., 1942.) 10*s*.

THIS "entirely revised edition" retains many of the features which characterized the earlier editions. The rapid growth of organic chemistry, however, makes the task of the reviser ever more difficult, and although an earnest attempt has undoubtedly been made to bring this 'classic' up to date by the addition of new chapters, after forty years surely nothing less than complete re-writing and the provision of an entirely new set of diagrams can erase the inevitable signs of age. Much material of purely historical significance might have been sacrificed; petroleum as an illuminant is relatively unimportant compared with its value as a motor fuel. The latter topic receives far too little attention, an omission which is all the more serious in view of the growing importance of the petroleum industry as a source of basic organic chemicals such as olefines, butadiene, isopropyl alcohol and acetone. No mention is made of the direct production of nitroparaffins from hydrocarbons, and subjects such as plastics and catalytic hydrogenation are given inadequate treatment. Greater care might have been taken in ensuring accuracy, particularly in the new chapter on compounds of biological importance; xanthophyll is not an oxide of carotene, ergosterol has long been known to possess twenty-eight carbon atoms, and different molecular formulæ for cholesterol are given on different pages. E. R. H. JONES.

The Subject Index to Periodicals, 1941

Issued by the Library Association. Pp. x+204. (London: Library Association, 1943.) 77*s*.

THE Subject Index to Periodicals, 1941, issued by the Library Association, appears only some ten months after its predecessor, thus making up to some extent the loss of time incurred in 1940-41 and encouraging the hope that the Index can weather the storm without a gap in the sequence of its volumes or excessive delay in publication. This reduction of the time lag in publication is particularly welcome in some fields and should further enhance the value of the Index if it can be maintained or further reduced. The Continental periodicals previously indexed are no longer obtainable and their place has been taken by the following British and American publications, carefully selected by a sub-committee: *Anglo-Soviet Journal*; *Bulletin of the Friends' Historical Association*; *Bulletin of Spanish Studies*; *Comparative Literature Studies*; *Conveyancer*; *France Libre*; *Horizon*; *Modern Law Review*; *Music Review*; *Plastics*; *Religion in Education*; *Silk and Rayon*; *Soil Science*; *Transactions of the Leeds Philosophical and Literary Society*. As previously, the Index is compiled on the plan of the "dictionary catalogue", articles being entered under specific headings in alphabetical order. With some important exceptions periodicals covered by *Science Abstracts A* and *B*, the *Index Medicus*, *Agricultural Index*, *Engineering Abstracts* and *Index*, *Photographic Abstracts* and a few other specified publications are not indexed.

Textile Fibres under the X-Rays

By Dr. W. T. Astbury. Pp. 54. (London: Imperial Chemical Industries, Ltd., 1943.) n.p.

WE all know the remarkable progress made by Dr. Astbury in the X-ray study of textile fibres. What some of us do not realize, however, is the elegance of the structural relations underlying this new knowledge; many of them are enmeshed in a large and somewhat obscure body of literature. In this monograph (of which the publishers say that, owing to the paper restrictions, they cannot distribute copies freely in Great Britain) the essentials of the subject are presented with exceptional clarity, brevity and charm. It is just enough to whet any inquirer's appetite, and the well-produced plates add the appropriate garnish. All the X-ray photographs are of the original size, enabling the rotation formulæ illustrated in the first two figures to be applied directly. F. IAN G. RAWLINS.

DEVELOPMENT OF BOTANICAL INVESTIGATIONS AT ROTHAMSTED

AT the meeting of the Linnean Society on June 24, Sir John Russell and three of his staff outlined the history of the botanical work at Rothamsted Experimental Station since it was founded one hundred years ago.

In a rapid survey Sir John Russell showed how the association of Sir John Lawes—an essentially practical man—and Sir Henry Gilbert—a research worker with a genius for detail—led to the establishment of agricultural science on a firm basis in Great Britain. At the beginning the chemical aspect of crop growth was the only one considered, and much of the early work was determined by the controversy on the nitrogen nutrition of plants. Liebig emphasized, quite rightly, the value of mineral fertilizers, but maintained that the use of nitrogenous manures was unnecessary, as the plants obtained most of their nitrogen from the air. Lawes and Gilbert disagreed, and proved the value of nitrogenous fertilizers on the wheat plots on Broadbalk Field, obtaining striking increases in height and yield with progressively greater applications of ammonium sulphate. The problem of the source of the nitrogenous compounds in the soil was worked on by Prof. Robert Warington who, though primarily a chemist, diagnosed the activity of two forms of soil organism, one of which converted ammonia into nitrite, and the other transformed the nitrite into nitrate, thus completing the work of nitrification. He was not, however, able to isolate the two forms of bacteria concerned.

From 1856 onwards the botanical side began to emerge, primarily from studies of changes in the herbage of grassland induced by differences in manuring when the same treatment was continued year after year. Also, close observation was kept on the weeds in the arable crops, showing differences related to the varied manuring. Until the death of the founders in 1901 the botanical side retained this status of purely observational work on the fields.

With the coming of Sir Daniel Hall as director, the laboratory side of the work began to extend. There was a fuller recognition that plants are living things and therefore no two are quite alike, either in their form, development or response to similar conditions of nutrition or environment. Also it was recognized that no two areas of soil in the same field are absolutely identical, and that consequently it is not possible to adopt the same technique in dealing with plants as with chemical substances with their fixed reaction to any particular set of conditions. The recognition of these basal facts led to the gradual development of various departments concerned with different aspects of agricultural science. On the physical side it was realized that soil is not simply a supplier of food, but is a source of water and also provides a definite environment, specially in connexion with the supply of air to the roots of plants. Statistical methods were applied by Prof. R. A. Fisher to the lay-out of plot experiments, whereby smaller areas could be utilized, more treatments dealt with in a single experiment, and more accurate results obtained. On the bacteriological side the effects of partial sterilization on the soil microflora were worked out and, more recently, practical methods have been developed for inoculating lucerne seed with the appropriate nodule organisms.

In the earlier days attention had been focused on the importance of the 'major' elements, as nitrogen, potassium and phosphorus, in plant nutrition. Since 1906 the relation between 'minor' elements and plant growth has been under continuous consideration by Dr. W. E. Brenchley and her colleagues. The term 'minor' element is used to indicate those elements of which extremely small amounts are sufficient to influence the plant, either beneficially or harmfully. It in no sense indicates that these elements are minor in importance. In fact biologists and agriculturists alike are becoming alive to the fact that these elements are of the greatest importance in the metabolism of the plant, and in this connexion they are attracting attention much as vitamins have done in the economy of animal life. The complex chemical composition of soil renders it a very difficult medium on which to test the effect of minor elements on plants, as no real control can be exercised on the elements available to the roots. Such control is afforded by the nutrient solution method, and all the initial research has been carried out in this way.

Attention was first directed to a group of five minor elements already associated with plant growth in one way or another—copper, manganese, zinc, arsenic and boron, tested over a wide range of concentrations. Toxicity was easily shown—copper and arsenic being about ten times more deadly in the stronger concentrations than any of the others, manganese and boron being required in relatively large amounts to be lethal. Further work with copper, nickel and cobalt showed the varying response of individuals to concentrations on the border line of toxicity. In the presence of solid particles such as quartz, sand, or soil the poisonous action is greatly reduced. Consequently, plants growing in soil may be able to make normal growth in the presence of an amount of a poisonous substance which would kill, or at least seriously damage, a similar plant in nutrient solution.

Stimulation with minute traces of elements was far more difficult to demonstrate, though some indication was obtained. Following up an accidental clue obtained in 1921, Dr. K. Warington proved conclusively that in the absence of a trace of boron, growth of broad beans was completely checked, owing to atrophy of the meristematic points and subsequent breakdown of the tissues. The growing points of stems and roots, the flower buds and also the meristematic tissues of the nodules on the roots are all affected. Many other plants were also shown to require a trace of boron, and the work and literature on the subject has become very extensive. Various obscure plant diseases, hitherto classed vaguely as 'physiological', are now known to be due to boron deficiency. Heart rot of sugar beet, raan of turnips, topsiekte of tobacco, and other crop diseases are curable or prevented by the addition of about 12–20 lb. per acre of borax.

The fertilizer Chilean nitrate contains a number of minor elements, of which boron and iodine are the most prominent. The quantity of boron is adequate for the needs of plants, but so far it has not been possible to demonstrate any agricultural value of the iodine, though it is still possible that the feeding value of the crops may be improved by the absorbed iodine. Molybdenum is also present, and claims have been made elsewhere that it is essential for tomatoes. The results so far obtained at Rothamsted have been variable, though it is possible that molybdenum may hasten the ripening of tomatoes.

The more work that is done on minor elements the more complex the problem becomes. The cumulative evidence seems to suggest that deficiency symptoms are not always entirely the result of an inadequate supply of some critical element, but may also be bound up with other factors at present not fully recognized. Future work will doubtless have to be concerned with these factors as well as with the direct influence of minor elements on plant growth.

The recent bacteriological work at Rothamsted under Dr. H. G. Thornton has largely been related to the nodules produced on leguminous plants. It is well known that these nodule-forming bacteria fall into groups that are in general specific to certain groups of species or genera among their host plants. The bacteria are further subdivided into strains within each host-specific group. If a number of bacterial cultures are isolated from nodules on a single host species, they are found to vary very much in the benefit they confer on their host plant through nitrogen fixation. At one end of the range there are often to be found strains that are largely ineffective in this respect—scarcely increasing the nitrogen content of their host plant. Such ineffective strains are particularly noticeable among the nodule bacteria of clover and of peas and beans. A survey is now being made of the distribution of ineffective clover nodule bacteria in Great Britain. These are found to be particularly abundant in the poor sheep pastures of hill districts in Wales, the north of England and Scotland. The study of these strains has the improvement of the clover growth in such pastures as its ultimate object.

Anatomical study of the nodules produced by ineffective strains shows that these have a much smaller content of infected tissue than do effective nodules. In addition, the tissue disintegration and dissolution of the contained bacteria, which eventually occur in all nodules, take place much earlier in those produced by ineffective strains. If these factors are taken into consideration the amount of nitrogen fixed by a unit volume of bacterial tissue in a given time is the same for 'effective' and 'ineffective' strains. The latter are ineffective because they do not grow so well or last so long in the nodule as do the effective strains. It has been found that individual plants vary greatly in their response to the nodule bacteria. In a few plants, bacteria belonging to a normally ineffective strain can produce nodules of normal size and can benefit the plant. The converse can happen with a normally effective strain of the bacteria. There is some evidence that this variation in the response of the host legume is hereditary. If this is confirmed, it raises the hope that varieties of clover can be developed giving an effective response to infection even by a normally ineffective bacterial strain.

It may also be possible to mitigate the effects of a population of ineffective strains of nodule bacteria in the soil by supplying effective strains through seed 'inoculation'. Here, however, a difficulty arises owing to the acute competition that takes place in the root surroundings between different strains of nodule bacteria. Strains that compete successfully with others are those having a high initial multiplication rate in the soil. Strains have now been found that combine this high multiplication-rate with effectiveness towards their host plant. Such strains can compete successfully with ineffective strains in the soil and should thus be useful for the purpose of 'inoculation'.

Mr. F. C. Bawden proceeded to describe the investigations that have been made into the precise nature of those mysterious entities known as viruses. Viruses can conveniently be defined as obligately parasitic pathogens, too small to be resolved by ordinary microscopical methods. Their scientific study dates back to 1892 when Iwanowski, a Russian botanist, demonstrated that tobacco mosaic is a virus disease.

During the next forty years the number of recognized virus diseases increased steadily, and considerable progress was made in symptomatology and in discovering the means whereby viruses are transmitted, but little or no information was gained about their nature. They were generally believed to be the smallest living organisms, essentially similar to bacteria, though with the unfortunate properties of being invisible and unable to grow in culture media. During the last seven years, however, specific proteins have been isolated from plants infected separately with several different viruses, and all the available information suggests that these proteins are the viruses themselves. The size of the protein particles varies with different viruses, but all so far examined have particles with weights equivalent to molecular weights in excess of a million.

Tobacco mosaic virus was the first to be isolated, and is now recognized as a liquid crystalline nucleoprotein, in which X-ray diffraction has revealed a regularity of structure previously unsuspected in solutions. The greatly elongated particles found in a purified preparation of tobacco mosaic virus may be, in part at least, an artefact produced during the course of purification.

Other viruses, isolated from tomato, cucumber, potato and Hyoscyamus show similar optical phenomena, but tomato bushy stunt virus differs in that the solutions show no unusual optical properties, but when precipitated isotropic dodecahedral crystals are formed.

Most viruses spread readily from the point of entry throughout the infected plants to give a systematic infection, but in tobacco necrosis the symptoms are restricted to necrotic lesions on the inoculated leaves. Several different viruses and virus strains can cause the symptoms of tobacco necrosis, but on purification they precipitate in various ways.

All viruses so far purified have widely different properties and stabilities and are transmitted in different ways, but all are chemically similar nucleoproteins only varying significantly in their phosphorus and carbohydrate content.

X-ray analyses have shown that the viruses are in a sense double crystalline, and that the virus particles, even when in solution, do not contain any water. It is their chemical simplicity, the regular arrangement of their constituent units and their inability to take up water, that most sharply separates viruses from even the simplest known organisms. The intracellular inclusions so characteristic of many virus diseases may prove to be insoluble complexes formed by the virus combining with some constituent of the infected host plant.

The papers were followed by a short discussion, opened by Dr. B. Dyer, who recalled his first meeting with Lawes and Gilbert in 1865, beginning an association with Rothamsted which has lasted to the present day.

THE OPERATIONAL CALCULUS

By PROF. H. T. H. PIAGGIO

AT the thirtieth meeting of the Indian Science Congress, held at Calcutta during January 2–4, Dr. S. C. Dhar, president of the Section of Mathematics and Statistics, discussed certain developments of mathematics in the last thirty years. Mathematical research is now so varied that it is difficult for an active worker in one branch to follow progress in other branches. It is, therefore, very valuable when a specialist can give an intelligible summary of the chief results obtained in some particular subject. Dr. Dhar selected "Operational Calculus and Automorphic Functions". In what appears below, Dr. Dhar's address has been supplemented by matter obtained from other sources.

The operational calculus is associated particularly with the names of Oliver Heaviside ("Electromagnetic Theory", 1893, 1899, and 1912), T. J. I'A. Bromwich, and J. R. Carson. Heaviside's object was to solve certain problems concerning electrical circuits, which led to a set of differential equations. Self-taught and working in isolation, he not only took no trouble to conform with recognized mathematical methods, but even seemed to take a delight in apparently unsound arguments. "Mathematics," he said, "is of two kinds, Rigorous and Physical. The former is Narrow: the latter Bold and Broad. To have to stop to formulate rigorous demonstrations would put a stop to most physico-mathematical enquiries. Am I to refuse to eat because I do not fully understand the mechanism of digestion ?"

This attitude aroused great opposition from the pure mathematicians. But there was something to be said on their side. (Heaviside himself said, "even Cambridge mathematicians deserve justice".) Ever since the introduction of the differential calculus, mathematicians had been tempted to rely on intuition rather than on rigid proof. By this means they obtained speedily a large number of results, but unfortunately many of these were not altogether accurate. The error generally consisted of the assertion as a universal truth of a theorem which actually held good only in certain conditions. Only in the later part of the nineteenth century had Weierstrass and Dedekind succeeded in abolishing the slipshod methods of the preceding two hundred years, and in returning to the high ideals of mathematical rigour held by the ancient Greeks. To those who took part in this reform, Heaviside's methods seemed a kind of mathematical blasphemy, a wilful sinning against the light. Yet Heaviside's results were always correct! Could a tree be really corrupt if it always brought forth good fruit ?

It may be recalled that a similar situation arose early in the nineteenth century. Fourier expanded functions in an infinite series of harmonic terms, and applied the results to problems in the conduction of heat. The results were very valuable, and yet the methods by which they were obtained were unsound, as was pointed out at the time by Lagrange. The investigation of the reason for the success of Fourier's work was very difficult, but it ultimately led to great advances, and may be taken as the starting-point of the theory of functions of a real variable. Possibly with this in mind, pure mathematicians of the twentieth century, when the battle for rigour had been won and the victors could afford to take up a more tolerant attitude, began to show more appreciation of the "Bold and Broad". Prof. G. H. Hardy, some time before 1914, expressed the view that what analysis then needed was a twentieth century Euler, capable of trying daring experiments with what one might call "conjuring tricks in mathematics"; the details of justification might then be filled in by workers at their leisure.

However, the task of justifying Heaviside's methods proved unexpectedly difficult. His basic idea was to treat the differential operator p as an algebraical symbol, and to pass from a differential equation to a subsidiary algebraic equation which had the distinctive property of incorporating the initial conditions. The solution of this equation was resolved into partial fractions, or expanded in inverse powers of the operator, which were interpreted as integrations. Sometimes fractional powers of the operators occurred, and these were interpreted by a rule which was a natural generalization of that for integral powers. Unfortunately, as the work proceeded, more and more apparently arbitrary rules were needed to reach the correct result. Dr. Bromwich was the first to give any rational explanation of these rules, but he found it necessary to adopt an entirely different approach, namely, the use of complex variables and contour integrals, a method first used for differential equations by Cauchy. A German, K. W. Wagner, independently studied the problem at the same time (1916) and obtained some of Bromwich's results. Since then operational methods have been generally accepted, although there is still some doubt concerning their application to partial differential equations. Bromwich considered that Heaviside must be ranked with the greatest constructive mathematicians of the nineteenth century, far outstripping the finest senior wranglers of the Mathematical Tripos in his amazing skill in manipulation.

Another justification of Heaviside's work was given in 1917 by an American, J. R. Carson, using only the real variable. By means of the equation

$$\phi(p) = p \int_0^\infty e^{-pt} f(t)\, dt,$$

he set up a correspondence between $f(t)$, a given function of the time, and its operational representation or symbolic image $\phi(p)$. From this Carson derived a set of theorems of the utmost importance in operational calculus and in the solution of electrical problems. Further developments are due to many writers, in particular Van der Pol (from 1929). A recent book is Carslaw and Jaeger's "Operational Methods in Applied Mathematics" (1941). Besides the primary application to differential equations, operational methods give a simple method of obtaining relations between functions by finding the much simpler relations which often hold between the symbolic images and then transforming the results.

Dr. Dhar also dealt, but more briefly, with automorphic functions, which may be defined as functions which remain invariant when subjected to a group of bilinear transformations. Automorphic functions are a generalization of trigonometric functions, which are periodic, and of elliptic functions, which are doubly periodic. The pioneer work was due to Poincaré (1881) and Klein (1882). Recent advances have been due to E. T. Whittaker and his pupils.

PRESERVATION OF MUSEUM OBJECTS IN WAR-TIME*

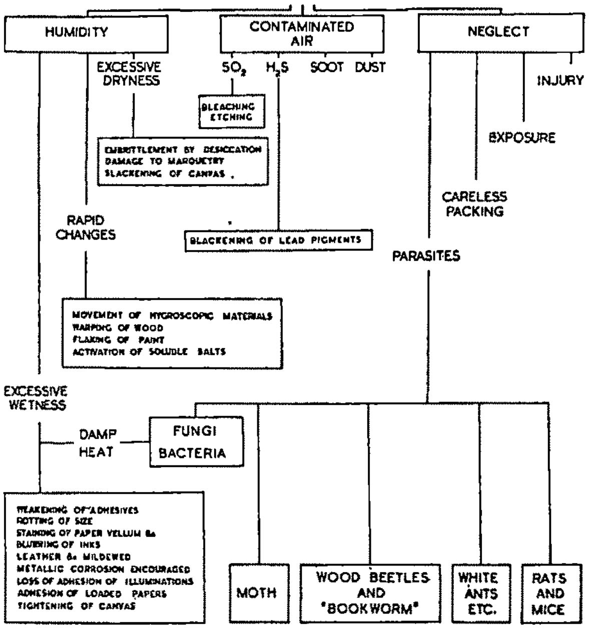
By DR. H. J. PLENDERLEITH

Research Laboratory, British Museum

THE care of the national treasures in museums and galleries is a very great responsibility at any time, but particularly so in war-time. Whatever the nature and size of the collection, modern warfare presents the curator with a two-fold problem, involving, first of all, measures to circumvent the immediate disaster of bombing and, secondly, measures to prevent the gradual deterioration which is so often the accompaniment of prolonged storage.

Early in the War of 1914–18, as the staffs of museums became depleted, it seemed likely that museum specimens might suffer more from the lack of expert attention than from high explosives, aerial warfare being at this time in its infancy. But in the summer of 1915 the first bombs fell in London. Sir Frederick Kenyon[1], who was then director of the British Museum, has described the Herculean task that had to be faced in evacuating a large proportion of the collections to a new Post Office section of the London underground tube railway system, which had been hurriedly prepared to receive them and where they were to remain for almost two years. It seemed that little damage resulted from this double removal, but nevertheless in 1919 the Trustees thought it advisable to invite the Department of Scientific and Industrial Research to make a scientific examination of the collections and give advice and assistance in regard to the restoration and preservation of objects. Dr. Alexander Scott undertook this investigation on behalf of the Department; a small temporary laboratory was equipped at the British Museum and a considerable amount of introductory experimental work carried out, the practical applications of which were embodied in three reports[2], which had a wide circulation.

CAUSES OF DAMAGE TO MUSEUM OBJECTS



Dr. Scott's method was to study the causes and symptoms of instability and to work out methods of treatment which "could be regarded as safe if applied with ordinary care and discretion". There were to be no secret processes. Help was to be freely afforded to all who had the care of precious objects of antiquity and works of art. It was thus possible to obtain a wide experience in dealing with museum objects and materials of all kinds and to obtain an insight into the technical requirements of museums and picture galleries. This was essential because stability is, after all, a relative term and conservation only begins to have practical significance when the conditions under which things are to be conserved are clearly defined.

The new outlook was welcomed almost universally in the museum world at home and abroad. The traditional distrust of science gradually disappeared and with it many outworn conventions of technique which had proved to be stumbling-blocks to progress. There was active support in Great Britain from the Museums Association[3]. The next few years were marked by the extension of the laboratory idea abroad, and the League of Nations[4] organized a series of conferences for the special study of problems affecting the preservation of works of art and of antiquities. Individual workers made valuable contributions, and specialized laboratories (notably the Fogg Art Museum Laboratory[5], Cambridge, Mass., and National Gallery Laboratory, London) did much to enrich the common fund of technical knowledge which was ready to hand and had merely to be mobilized and assorted in preparation for a second world war.

Early in 1939, at the instance of the Standing Commission for Museums and Galleries, a committee was convened representing the national museums, picture galleries and libraries under the chairmanship of the director of the British Museum, Sir John Forsdyke. This committee considered at great length many aspects of the preservation of museum objects in war-time, and the findings were incorporated in a handbook entitled "A.R.P. in Museums, . . ."[6]. This booklet was timely in its appearance and of great service in helping curators all over the country to mature plans for the protection of their collections in advance of the approaching catastrophe of the autumn.

It is no easy matter to make adequate preparations for the safety of a collection of museum objects, because there are so many divergencies of type. There are endless variations of material, structure, age and stability. Some objects are by nature perishable; others become so from a variety of causes. Before it is possible to work out satisfactory methods of protection, the relative frailty of objects must be studied, the symptoms of decay recognized, and some knowledge is also required of the varying conditions under which deterioration is aggravated or arrested—precisely the line of research inaugurated by Dr. Scott at the British Museum twenty years previously.

The main causes of decay are fortunately few in number and can be conveniently summarized (see accompanying table). It may be stated on simplest analysis that decay arises either from internal causes (for example, the presence of crystalline salts in the pores of stone) or from causes which are external (such as excessive humidity in storage rooms), and when decay is already taking place from internal causes, exposure to heat and moisture has usually the effect of accelerating the action and intensifying the damage.

---

* Substance of Friday evening discourse at the Royal Institution on May 21.

Damp promotes the mildewing of books and papers with consequent staining and disintegration. It also promotes the corrosion of metal objects. Leather is very susceptible to attack by moulds, which grow most actively in damp surroundings. Uncontrolled changes of humidity and temperature are most destructive to paintings whether on canvas or on panel, causing cracking and blistering of the paint, and for this reason pictures are as a class among the most delicate of museum objects. These considerations have all to be taken into account in arranging for packing and transport, and in deciding upon suitable storage accommodation.

Fortunately there remains a large category of objects which are resistant to damp and impervious to atmospheric changes. Such things as porcelain, baked clay, most kinds of glass, many metals, stone monuments free from salts, natural history specimens in spirit, etc., and these (with any packing that may be necessary) may be consigned to the cellars with a fair prospect that they will not suffer deterioration by neglect.

It will be obvious from the preceding statements that any storage space which affords safe protection from the effects of bombing can always be utilized; if the temperature and humidity can be controlled at reasonable levels its value will be infinitely greater, and if constant atmospheric conditions are obtainable in the right degree it will satisfy the exacting requirements of a permanent repository for the most delicate material.

Looking back over the years of peace, two further lines of investigation stand out as of the first importance to the preservation of museum objects in wartime. These are Macintyre's work on atmospheric humidity and Groom and Panisset's studies on the growth of micro-organisms.

In 1929 Mr. J. Macintyre[7] (late of H.M. Office of Works) took hygrometric readings over a period of time (*a*) in the open air, (*b*) in a museum gallery and (*c*) in an exhibition cabinet within the gallery. This cabinet contained only some hygroscopic material (canvas). He found that the variations in relative humidity (R.H.) were much less extreme in the gallery than outside the building, and that within the cabinet no maxima and minima of humidity were recorded. The relative humidity in the cabinet had remained to all intents and purposes constant. The work was confirmed by further tests made at the British Museum by placing recording instruments in an exhibition case of considerable capacity (176 cub. ft.) which was not even provided with an air-tight door. The case had 88 sq. ft. of glass and the equivalent of textile lining. It was found after the short interval of time which was necessary to establish equilibrium that the hygrograph pen became almost stationary and a horizontal line was drawn across the chart.

Certain deductions may be drawn from this, which have a direct bearing on the packing of museum objects which are sensitive to damp.

(1) The presence of soft hygroscopic packing materials, such as cotton-wool, kapok, wood-wool and paper are beneficial in the steadying effect they have upon humidity within the box. Objects should be wrapped in tissue and nested in the soft packing. Such packing materials must obviously be dry, otherwise humidity will be stabilized in the box at a high level.

(2) It would be very unwise to open a box for inspection purposes when external atmospheric conditions are unsatisfactory, as this would allow access of moist air which would remain and encourage mildew growths.

Packing is very largely a matter of common sense. Special methods are required with machinery, heavy sculpture, paintings and large intricate objects. These should be anchored by struts of wood fixed inside the packing case, the final fitting being often a wedge-shaped piece of hard-wood screwed in position inside. When heavy objects are stored for any length of time, the elasticity of the packing materials may be impaired, so that specimens settle lower in the box and become loose. When this happens repacking is required before it is safe to contemplate transport.

Turning now to the question of storage, it may be asked whether it is possible to define atmospheric conditions which are entirely safe for all kinds of museum objects. In order to answer this we turn to an investigation conducted by the late Prof. P. Groom and Miss T. Panisset[8] in 1933 on the mildewing of binding materials. Of all the materials studied tanned skins were found to be the most susceptible to fungoid growth. Efforts were made to grow mildew on these over a wide range of humidity and temperature, and the lowest relative humidity at which growths were observed with the naked eye was 72·6 per cent, the corresponding temperatures (68–77° F.) being near the optimum. Twenty-four weeks actually elapsed between the first of a series of inoculations with young conidia and the appearance of growths. There seems justification, therefore, for regarding a round figure of 70 per cent R.H. as the upper limit beyond which the atmospheric humidity must not be allowed to rise (irrespective of temperature) if mildew growths are to be avoided. In point of fact, the constant conditions recommended for paintings are 60 per cent R.H. at 60° F., and while these conditions would of course be ideal for collections of any kind, variations of 5° and 5 per cent either way would not be deleterious in museum and library repositories. Where any doubt exists, tests of the humidity are readily made by the use of a whirling psychrometer, and it is important to take such observations at regular intervals in basements and strong-rooms, continuing at least until such time as it is evident that conditions are likely to remain satisfactory. If damp is excessive, measures are taken to improve ventilation, for example, by piercing walls and doors, using electric fans and heaters or the more efficient shelter heating units. For certain museum objects and paintings damp is disastrous, but excessive changes of humidity may be even more damaging. A temporary cure for varying humidity is to cut off completely all external ventilation and to condition the air in the room by heaters and fans[9]. This has the effect (*a*) of stabilizing the relative humidity and (*b*) of reducing it to the required degree at a temperature which is fairly constant, but the scheme can only be considered safe when under constant observation and psychrometric control. It is an emergency method, easily arranged at short notice where there is a suitable electric supply, but entirely dependent for success upon the human factor.

The main problem in basement storage is to avoid pockets of cool stagnant air, and skill is required in the

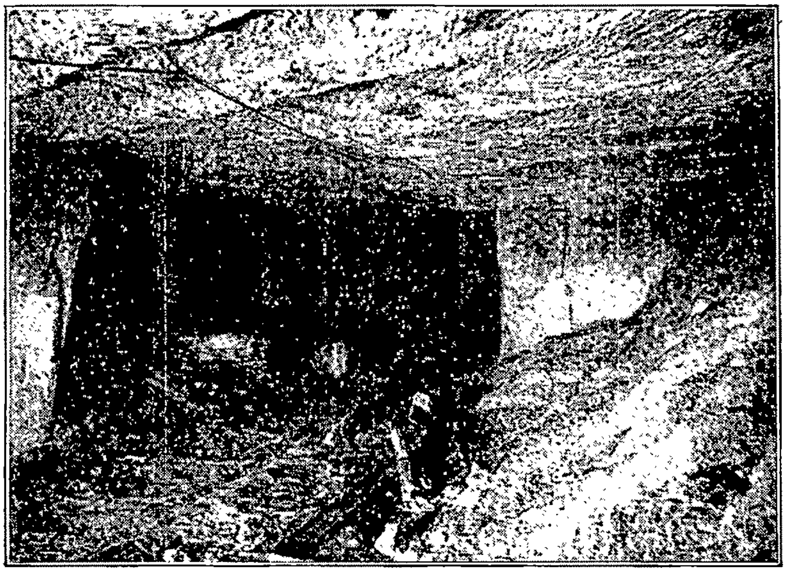


Fig. 1.

stacking of boxes and the fitting of any wooden racking that may be necessary. Boxes should always be raised on duckboarding or battens so that they are not in contact with the floor, and a free air space should be left next the walls. This provision is essential for safe storage in normal times, but in time of war when there is a possibility of flooding from hydrants or burst pipes, the question of drainage has to be taken into account in determining the height of wooden staging.

When book-racking is built adjacent to an outside wall, provision of several inches of air space at the back is very important. Openwork racking and shelving is safer than cupboard storage. Books should never be stored for any length of time in heaps even in a dry room because of their proneness to mildew and 'foxing'. There may be no option in an emergency, but any such arrangement should be of temporary duration.

Circumstances are different in the case of objects which are impervious to damp. Here it will be a question of preserving the labels by wax; they should be of the 'tie-on type and should be clearly written with a black waterproof ink. Organic packing materials are so far as possible excluded, and wooden boxes may be lined internally with waterproof paper and painted on the outside with 10 per cent copper naphthenate in paraffin oil, in order to minimize the tendency of the wood to rot.

Much ingenuity has been expended in designing special containers suited to various classes of material. For conditions which are reasonably dry, the plywood no-nail box has much in its favour. Where damp has to be feared, small air-tight galvanized metal containers have been employed for storing manuscripts. The manuscript is placed in the box, the air within being of the degree of dryness suitable for permanent preservation of the contents at the temperature of the storeroom, and the jointing is then made air-tight with a strip of soft solder. The curator of the Reading Museum has solved the problem of storing his collection of vellum documents by placing them in a couple of hundred dust-bins, each with a tar felt lid pressed over, and then the metal lid is pressed on and lashed firmly to the handles. Within each bin is a tin of dry silica gel inserted before the container is closed, and this absorbs excess moisture from the air. Access to the documents is occasionally necessary and a fresh tin of silica gel is then inserted before replacing the cover. Excellent reports have been received of the efficiency of the arrangement.

With the widespread development of aerial bombing it was increasingly obvious that no surface shelter could be regarded as safe. The London 'Underground' provided a partial solution for some museums; others, having objects that could withstand damp, took to deep tunnels in the chalk.

An early experiment in artificial tunnelling in a hillside in the country proved more costly than anticipated, but satisfactory housing was eventually obtained there for books, prints, drawings and manuscripts. To control the humidity within the desired limits, the intake ventilation duct was equipped with fans and a battery of electric heaters, and there was provision against the emergency of electrical breakdown by an independent auxiliary greenhouse heating equipment and manually operated fans.

When air is taken direct from outside, as in the above system, the control of humidity by heating may necessitate considerable variations of temperature, but when a bulk supply of saturated air is already available at a low constant temperature (a common

Fig. 2.

condition in certain caves and mines) it is possible to obtain the required humidity by raising the temperature to a fixed degree, and under favourable conditions this temperature may also approximate to requirements. Such a scheme has been applied successfully in certain disused underground workings. It involves the building of suitable chambers as repositories in the caverns underground, and these are each equipped with batteries of heaters and fans which pass the conditioned air into plenum systems within the repositories. This scheme lends itself particularly to the storage of paintings because of the area of dry wall space that the chambers afford, and the most striking example is no doubt to be found in the main National Gallery repository recently described by Mr. F. I. G. Rawlins[10].

When it is a case of storing valuable furniture, carpets, textiles, large quantities of irreplaceable books and manuscripts, antiquities and ethnographical objects of all kinds, the first essential is one of floor space, and to satisfy this requirement on an adequate scale, building and excavation are alike out of the question. For the cream of the collections of the British Museum and Victoria and Albert Museum, there was no option but to find sufficiently extensive underground workings in rock which could be waterproofed and in which the air could be fully conditioned as to temperature, humidity and ventilation. Nothing short of an undertaking of this magnitude could satisfy what had become, by the spring of 1941, an urgent requirement of great national importance. Before any valuables could be stored it would have to be demonstrated that conditions of 60° F. 60 per cent R.H. could be continuously maintained, and that there was adequate provision in the plant-room against the possibility of breakdowns. It was a question of perfection or nothing.

The choice of site presented many difficulties, as did the preparation of accommodation, but thanks to the Ministry of Works and Planning the ideal repository was brought into being within the remarkably short space of time of one year, and has since been used to capacity (Figs. 1 and 2).

The full value of the work which had been already accomplished in devising standard forms of package and racking was now apparent; uniform series of boxes made for economy in storage space, and distribution is such that it is possible to have immediate access to any specimen by consulting the location inventory. Carpets are tightly rolled and sealed up in paper and they are stored on staging covered with chicken-netting; most of the smaller textiles are suspended on coat-hangers on avenues of horizontal rods, the more fragile under 'Cellophane' envelopes. Fluorescent lighting is available in the inspection rooms and compressed air is laid on to facilitate insecticidal spraying, should moth be discovered.

A feature of the plant room, which is separated from the main repository by strong-room walls, is the arrangement made for the remote observation of conditions in the repository and for the remote control of machinery connected with the conditioning of the air. The engineer-in-charge has before him Cambridge recorders which show at a glance the conditions of temperature and relative humidity at various selected points in the store, and by operating the remote controls he can adjust the setting of the automatic switch gear, if for any reason it should be necessary to vary the air supply in quality or in volume.

It is no exaggeration to state that in every detail of storage there is indication of forethought and skilful planning, and that the directors of the British Museum and Victoria and Albert Museum, with the support of their respective staffs and the Ministry of Works and Planning, have jointly been able to contrive and bring into actuality a museum in the bowels of the earth, which, from the point of view of conservation, is as fine as anything known above ground, either in Great Britain or elsewhere. Much valuable experience has been gained and it is a comforting reflexion that this knowledge will be applied in the remodelling of our museums after the War, so that the national treasures can be adequately housed and suitably displayed.

OBITUARIES

Sir Thomas Middleton, K.C.I.E., K.B.E., C.B., F.R.S.

SIR THOMAS HUDSON MIDDLETON, chairman of the Agricultural Research Council and formerly professor of agriculture in the University of Cambridge, died at his home, Whyte House, Strawberry Vale, Twickenham, on May 14 at the age of eighty.

Sir Thomas was educated at Merchiston Castle School, Edinburgh, and at the Universities of Glasgow and Edinburgh. His first post (1889) was the professorship of agriculture at Baroda College, India. He held this until 1896, when he became lecturer in agriculture in the University College of Wales, Aberystwyth. Then, in 1899, he was appointed to the professorship of agriculture at Durham College of Science, and, in 1902, to the professorship of agriculture in the University of Cambridge. The Department of Agriculture, as it was then described, was a young one, inadequately staffed and housed, and struggling to find its place in a University which at that time looked upon applied science with almost as much suspicion as the farmers of the Eastern Counties of England. Agriculture in Britain had drifted into a pitiably depressed condition, and large areas of land were passing out of cultivation. To check the prevalent 'tumbling down' of good arable land to grass, he set in train a series of demonstrations in Cambridgeshire and the surrounding counties on the technique of laying down land to grass with appropriate seeds mixtures. He also instituted trials to determine which were the best varieties of potatoes for growing in the Eastern Counties and to demonstrate, among other things, the value of a 'change of seed'. This was particularly congenial work to him, for his home training on Rose Farm in the Black Isle, Cromarty, had provided him with an exceptionally thorough knowledge of the crop. These demonstrations soon proved to be of great value to the farmers of the Eastern Counties and went far to dispel their mistrust of everything connected with laboratories and experimental farms.

Middleton's stay in Cambridge was a short one, for in 1906 he accepted the post of assistant secretary of the Board of Agriculture. It is no secret that he had misgivings about the advisability of doing so, and his friends, realizing how much his interests were bound up with an open-air life, did their best to dissuade him from taking this step by pointing out that the Board, at this time, had only a somewhat tenuous interest in education, and no vision whatever of the part research work could play in the development of agriculture; but the view that he could do more for agriculture as a Government official than as a university professor won the day.

This post he held until 1919, acting during the last two years of his tenure as deputy director general of the Food Production Department. The campaign he then became responsible for, hurriedly planned as it inevitably was, added the produce of approximately an extra three million acres to the national food supply in spite of a great shortage of labour, fertilizers and machinery. The full story of it is told in his book "Food Production in War" (Oxford, 1923).

With the coming of peace in 1918, Middleton was appointed a commissioner under the Development and Road Improvements Funds Acts of 1909–10. He continued to serve the Development Commission until 1941, becoming its vice-chairman in 1929. His tenure of office was broken into in 1926–28, when his wide experience of agricultural administrative work and his knowledge of agriculture in India was put at the disposal of the Royal Commission on Agriculture in India.

In 1938 Middleton was appointed chairman of the Agricultural Research Council by a committee of the Privy Council for the Organization and Development of Agricultural Research, after consultation with the Royal Society. He was ideally fitted for guiding a Council consisting of scientific men with no special knowledge of agriculture, and agriculturists with an equally limited outlook so far as scientific matters were concerned, for his work had brought him into contact with the research staffs of practically all of the agricultural institutions in Great Britain, and he never missed an opportunity of discussing with them, no matter what the subject, the investigations they were engaged upon. A wide general knowledge of the more important of the sciences bearing on agriculture made this possible and put him in a position to see most of the problems of agricultural development, as the directors of research institutes have to, from both the scientific and practical points of view.

Of the honours which fell to Middleton, two were especially valued. One of these was the fellowship of the Royal Society, awarded in 1936; the other was the Gold Medal of the Royal Agricultural Society, given for distinguished services to agriculture. He was, fittingly, its first recipient. The Universities of Aberdeen, Edinburgh and Wales conferred the LL.D. and Reading the D.Sc. upon him. In 1913 he was made C.B.; the honour of K.B.E. came in 1918, and K.C.I.E. in 1929.

Endowed almost to the end of his life with the best of health and a fine physique, Middleton was capable of tiring out his staff and the visitors to his demonstration plots, and then returning to a strenuous evening's work in the laboratory or his home. But though he never seemed to allow himself any leisure, he found time for two hobbies: one was photography and wherever his work or his holidays took him he carried a camera; the other was gardening. In Cambridge, in somewhat difficult conditions, he maintained a first-rate collection of roses chosen, as they flowered in a local nursery, with the keen discrimination of an old-time florist and grown with the aid of combinations of the various artificial manures used in his farm demonstration plots.

He married Lydia Miller, daughter of the late Prof. Davidson of Adelaide; she died in 1934, leaving a son and a daughter.

ROWLAND H. BIFFEN.

Dr. Karl Landsteiner, For.Mem.R.S.

THE death of Dr. Karl Landsteiner on June 26 in New York has closed a career of singular eminence in the realm of medical research. He was born in Vienna on June 14, 1868; graduated in medicine in 1891 at the University there; and from 1909 until 1919 held the post of professor of pathologica anatomy in the University. After the War of 1914–18 he left Vienna to work in a hospital in The Hague and from 1922 until his death he carried out his researches as a member of the staff of the Rockefeller Institute in New York.

As a young investigator, Landsteiner was deeply interested in the problems of serology and immunology Together with Donath he made observations on the substance in organ extracts which lyses the strictly homologous red cells, and which he and his co-worker identified as Metchnikoff's macrocytase With Halban he studied the differences of fœta and maternal blood sera from the point of view of their lytic, agglutinating and bactericidal properties Donath and Landsteiner in 1904 and 1905 made a notable contribution to knowledge of the role of intravascular lysis in the pathogenesis of paroxysma hæmoglobinuria. But the chief work of Landsteiner at this early stage was the recognition of differences in human red blood corpuscles when obtained from different individuals, and the separation of the red cells into four well-defined groups characterized by their behaviour when exposed to the action of the two main types of agglutinins that are met with in human sera. A statement foreshadowing this work was made in a footnote to a paper on the anti-enzymic lytic and agglutinating action of blood serum and lymph, which is dated February 10, 1900. He was an assistant in the Institute of Pathology in the University of Vienna when, in 1901, he published his work on iso-agglutination and the blood groups. Even at this early date he was aware of the probable significance of his results for medico-legal purposes and in the practice of blood transfusion. The value of his pioneer researches on the subject was attested when, in 1930, he was awarded the Nobel Prize in Medicine.

The importance of this work has been abundantly proved during the present War in the avoidance of undesirable reactions by ensuring that the donor's blood is compatible with that of the recipient. In spite of every care, inexplicable reactions hav occasionally occurred, and it was Landsteiner and Wiener who threw light on these accidents when in 1940, they discovered a hitherto unsuspected antigen, the *Rh* factor, a symbol chosen because a similar antigen exists in the blood of rhesus monkeys This antigen is present in the red blood cells of 8 per cent of human subjects, and an importan extension of knowledge arising from its study ha een the elucidation of the cause of the hæmolytic næmia of newborn infants; this disease has been ound to be due to the production of a lysin in the lood of an *Rh*-negative mother when the fœtus has nherited the *Rh* factor from the father.

The first two papers by Landsteiner and E. Popper n the experimental transmission of poliomyelitis to nonkeys appeared in 1908 and 1909, and opened he way to intensive study of the mode of ransmission of the causal filterable virus and of its eutralization by a specific immune serum.

During the twenty years between 1917 and 1938, Landsteiner and his co-workers extended the observations of Obermayer and Pick on the changes in the immunological specificity of proteins which result from modifying their chemical and physical structure. This series of researches gave full rein to Landsteiner's creative and analytical powers; in particular, the ingenious experiments with artificially conjugated antigens and the corresponding immune sera have shed much light on the nature of the serological specificity of proteins and cell antigens.

The last years of his life were devoted to studies on allergic manifestations produced in experimental animals in response to simple chemical compounds such as picric acid and quinine.

The consistently high level of Landsteiner's achievements throughout the long period of his active life makes it natural to imagine that he knew little or nothing of the painful gropings after scientific truth which afflict lesser men. Although his work received recognition in many quarters—he was elected a foreign member of the Royal Society in 1941—he bore himself modestly, and indeed seemed to forget self-interest in his preoccupation with the problems upon which his mind was bent. His name is assured of a permanent place in the records of experimental medicine. G. F. PETRIE.

NEWS and VIEWS

The Wellcome Foundation: New Research Appointments

DR. C. M. WENYON will be retiring shortly under the age limit from the directorship-in-chief of the Wellcome Research Institution and the directorship of the Wellcome Bureau of Scientific Research. His association with the research laboratories founded by the late Sir Henry Wellcome has extended over thirty-six years, commencing at the Wellcome Tropical Research Laboratories in Khartoum in 1907. Among his many contributions to the literature of protozoology his "Protozoology—A Manual for Medical Men, Veterinarians and Zoologists" is outstanding. Dr. Charles H. Kellaway, at present director of the Walter and Eliza Hall Institute for Medical Research, Melbourne, has accepted the invitation of the Board of the Foundation to assume the directorship-in-chief of the Wellcome Research Institution and the Foundation's other research laboratories at home and overseas. His appointment will become effective as early in 1944 as the convenience of the governing body of the Hall Institute and transport arrangements from Australia will permit.

Dr. N. Hamilton Fairley will take over the directorship of the Wellcome Bureau of Scientific Research. However, as he is at present Colonel A.A.M.C. and is serving as director of medicine to the Australian Army in the Pacific, he will be unable to proceed to England until a later date. Dr. T. A. Henry will be retiring on August 31, after which the Wellcome Chemical Research Laboratories (London) will be merged in the Wellcome Bureau of Scientific Research referred to above. Dr. Henry's work in the field of plant alkaloids is well known, and his book, "The Plant Alkaloids", is regarded as a classic in this field. The laboratories under his direction have always specialized in the chemistry of tropical medical research and will continue to do so.

Dr. Erwin E. Nelson, at present director of pharmacology at Tulane University, New Orleans, has been appointed director of the Wellcome Research Laboratories at Tuckahoe, N.Y. Dr. Nelson, who graduated in medicine at the University of Michigan, was from 1919 until 1937 assistant professor, associate professor and then professor of pharmacology there. During that time he was lent to the U.S. Government for two years so that he might organize the Pharmacological Department of the Food and Drugs Administration. Plans are in view for the further development of the Wellcome Chemical Research Laboratories at Beckenham under Dr. Sydney Smith, and a considerable expansion of the Foundation's research activities is envisaged for the immediate post-war period. Various changes in the organization of the Laboratories will be made in order that the Foundation's own research plans, as well as those carried on in collaboration with Government Departments, the Therapeutic Research Corporation and other bodies, may be fully realized.

A Staff College for the Civil Service

IN NATURE of May 8 was published a leading article which raised what we regarded, and still regard, as pertinent questions for the committee appointed by the Chancellor of the Exchequer to examine the matter of the training of Civil servants. We pointed to the committee's terms of reference and asked why the possibility of establishing a staff college should have been given special prominence, and we went on to give our views as to why a staff college, *if it be the only means of entry into the service*, may have precisely the results which ought, at all costs, to be avoided. Nothing in what we said, however, decried or was intended to decry the value of a staff college if it be given its proper place in any scheme for the preparation of future administrators. Our point was that such a college should not be allowed to take the place of the universities, the technical colleges and the other educational institutions in which candidates for the Civil Service may gain their first qualifications. We hope, however, that the committee to which we have referred will study carefully a paper on the "Post-Entry Training for Administration from the Industrial Aspect" recently delivered to a conference of the Institute of Public Administration by Mr. E. S. Byng, vice-chairman of Standard Telephones and Cables, Ltd.

Mr. Byng not only traced the growth of the need for training in administration selected members of staffs and the encouragement given towards that end by professional institutions: he also pointed out quite clearly that in the staff college he visualized, the curriculum would be concerned with broad administrative problems, and would exclude subjects covered by ordinary training.

A National Administrative Staff College

MR. BYNG made it clear, too, that the outstanding feature of the scheme of a national administrative staff college was that it would be highly selective. No matter in what department—accounting, commercial, engineering and the like—candidates for admission had served, only those who had shown themselves likely to qualify for higher grades of administrative responsibility would be considered. Moreover, while the course would extend over five months, not more than one quarter of the time would be devoted to formal instruction. The remainder would be occupied by discussions, practical exercises directed to testing powers of exposition, of investigating problems, drawing up reports and so on. Already, Mr. Byng told his audience, the group responsible for this proposal claim that among some two hundred and fifty people who have been consulted (and they include members of the Government, both Houses of Parliament, representatives of the Civil Service, local government, industry and the universities) all but a few have expressed their approval. We are glad to note these opinions from varied sides of our national life because they reinforce another of the points made by Mr. Byng. It is that industrialists and business men are ready, if not anxious, for an all-inclusive staff college. They would welcome the idea that picked men from the Civil Service should study together with picked men from their own ranks. We believe there is much to commend the idea. The growth of large-scale organizations, and of quasi-public corporations controlling services previously rendered by private enterprise, have made the differences between business and the public services much less definite than they used to be. Indeed, the relations between the business world and the Government departments become more and more intimate and complex. The War has added strength to that tendency and there would be obvious advantages in bringing together what Mr. Byng calls "the future administrators of both worlds" during a critical part of their training.

Post-War Demobilization of Scientific and other Personnel

A DEFINITE step in preparation for the demobilization of scientific, technical and professional staff from the Services and from the war industries at the end of hostilities and for their redistribution in suitable occupations both at home and overseas has now been taken by the Minister of Labour and National Service in the appointment of a Committee of Inquiry, with Lord Hankey as chairman. The Committee includes Mr. J. S. Duncan, Deputy High Commissioner for Australia, and the Dominions of Canada, New Zealand and South Africa will be represented by observers. The terms of reference are: To consider and report upon the arrangements which should be made to facilitate the employment after the end of hostilities of men and women qualified to undertake responsible work in the professions o elsewhere, with particular reference to (*a*) th organization, premises and staff of the Appointment Department of the Ministry of Labour and National Service; and (*b*) the arrangements which should be made for co-operation between the Appointments Department and other organizations and institutions (including professional, industrial and commercia organizations) and universities, at home and abroad In addition to those named above, the Committee includes Mr. H. M. Barton, Sir Bernard Bowdillon Mr. J. T. Davis, Mr. R. H. Dobson, Sir William Fyfe Mrs. Mary Hamilton, Mr. Clement Jones, Dr. H Lowery, Mr. John McLean, Mr. Godfrey Mitchell, the Hon. Eleanor Plumer, Prof. R. V. Southwell, Mr H. V. Tewson, Mr. Henry Thirkill, and Mr. G. W. Thomson, with Mr. H. F. Rossetti and Mr. F. M. H Markham, Ministry of Labour and National Service, as secretaries.

Coal Carbonization and the Economy of Britain

THE Institute of Gas Engineers held its eightieth annual general meeting in London on June 9, and the president, Mr. E. V. Evans, surveyed the industry of coal carbonization and its place in the war and post-war economy of Great Britain. To the general public, coal is just something to burn, but in the last generation we have seen the oil industry convert a raw material into a great variety not only of fuels but also of chemical products. To-day it is generally agreed that the coal industry must do likewise. The gas industry, of all fuel industries, so far has developed the processing of coal to the greatest extent. Mr. Evans' address revealed the far-reaching ramifications of the industry in the national fuel economy. But the section which seems to merit most careful scrutiny is the discussion of what may be anticipated from a co-operative scheme in which the public utilities co-operate instead of competing in the supply of electricity and gas, each supplying the public with its product in directions for which it is most fitted. The argument assumes the existence of a town of 200,000 inhabitants with the services normally developed and with prices as at present. It assumes that in three stages conditions alter in a normal manner leading to a result which may be summarized as follows: Consumption of gas would increase fourfold, while average price per therm would fall from 10·4*d*. to 6·22*d*. Consumption of electricity would double and average price fall from 0·98*d*. to 0·7*d*. per unit. Fuel bill for the average domestic consumer would fall from £17·9 to £16. Transport of solid fuel and ash through streets would fall to less than one fifth. The total amount of coal consumed for fuel and power would be reduced from 580,000 tons to 517,000 tons. Atmospheric pollution would be practically abolished, and recovery of by-products—tar, benzole, sulphur and ammonia—increased about fourfold. These gains require only the application of existing and technical knowledge, directed according to a national plan for the efficient use of coal.

Association of Special Libraries and Information Bureaux

THE report of the proceedings of the seventeenth conference of the Association of Special Libraries and Information Bureaux held in London during November 7–8, 1942, has now been issued. It conains the papers presented at the meeting with a brief record of the discussions and in addition Mr. C. S. Orwin's paper "Agriculture and the War Stimulus", which owing to his absence was omitted from the programme. Mr. Headicar's paper "War-time Problems in Books and Binding" and Miss E. M. R. Ditmas' paper "The Special Library in Time of War", together with Sir Richard Gregory's opening address "International Systems and Standards", were not included in the reprints issued in pamphlet form for use at the Conference. In addition to the summarized discussions, the pamphlet includes reports submitted from the National Central Library and the Citizens' Advice Bureau. The eighteenth annual conference of the Association will be held in the rooms of the Royal Society, Burlington House, London, W.1, on September 18 and 19. Particulars of the programme will be available later.

Public Health in Honduras

The January issue of the *Boletín de la Oficina Sanitaria Panamericana* contains an article on this subject by the Director of Public Health, Dr. P. H. Ordónez Días, who states that public health in Honduras is making notable progress since most of the people have become health conscious. Sanitary requirements, including health certificates for employees, have been enforced in public eating and drinking places and all others in which close contact with the public is required. A Biological Institute has recently been created for the preparation of serums and vaccines. The anti-venereal campaign has been intensified by the use of arsenical preparations. In spite of free distribution of anthelmintics, infestation by intestinal parasites is still prevalent. Only sporadic cases of malaria were observed. The milk station deals with a hundred children daily and distributes 163,332 bottles and 15,394 quarts of milk during the year, with the result that the child mortality in those attending the milk station was 68·2 as compared with 105·6 for the whole republic.

Earthquakes in the Pacific

The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has made a preliminary determination of the epicentres of three recent earthquakes in the Pacific Ocean. The first of these, on March 15, 1943, occurred at 4h. 47.9m. U.T. at an epicentre near latitude 10° N., longitude 142° E., which is in the bed of the ocean to the north-east of Fuhaesu in the Caroline Islands. The second earthquake, also on March 15, occurred at 22h. 59·2m. U.T. at an epicentre near latitude 14° S., longitude 174° W., which is in the bed of the ocean to the south-west of Savaii, Samoa, and north-east of Fiji. This earthquake had a depth of focus in the neighbourhood of 300 km. The third earthquake occurred on March 21 at approximately 20h. 35·4m. U.T. from an epicentre near latitude 6° S., longitude 146° E., which is on land in the north-east of the island of New Guinea. The exact location is just south of Astrolabe Bay and the coast town of Dein. All these earthquakes occurred in well-known seismic regions, and all interpretations and calculations are tentative, the data being received from seismological observatories to Tucson, Sitka, Honolulu, Wellington, Pasadena, Fardham, Sydney, Buffalo, Brisbane and Apia.

Announcements

The Zoological Society of London has arranged a course of popular lectures on natural history to be given at the Society's offices in Regent's Park, London. Admission is by ticket obtainable by post or at the Zoological Gardens on the day of the lecture. The first lecture will be given by Sir John Graham Kerr, who will speak on "A Naturalist in the Gran Chaco, South America", on July 28 at 3 p.m.

The following appointments, promotions and transfers in the Colonial Service have recently been made: H. S. Darling, plant protection officer, Palestine; M. Landau, assistant veterinary officer, Palestine; A. J. Kerr (agricultural officer, Uganda), senior agricultural officer, Uganda; E. T. Fern (veterinary officer, Northern Rhodesia), deputy director of veterinary services, Northern Rhodesia; J. A. N. Hobday (chief veterinary officer, Bechuanaland), director of veterinary services, Northern Rhodesia.

The Royal Society of Arts offers a prize under the Thomas Gray Memorial Trust, the objects of which are "The Advancement of the Science of Navigation and the Scientific and Educational interests of the British Mercantile Marine". The prize is of £50 and is open to any person of British or Allied nationality who may bring to the notice of the Society an invention, publication, diagram, etc., which in the opinion of the judges is considered to be an advancement in the science or practice of navigation, proposed or invented by himself during the period January 1, 1938–December 31, 1943. Entries which have already been considered by the judges in the years 1938–42 are not eligible for further consideration unless they have since been materially modified. Competitors must forward their proofs of claim between October 1 and December 31, 1943, to the Acting Secretary, Royal Society of Arts, at the above address.

According to the *Journal of the American Medical Association* of March 6, the Foundation for the Study of Cycles, New York, a non-profit organization created to foster, promote and conduct scientific research on rhythmic and periodic fluctuations in any branch of science, announces the offer of a medal to the person who, during 1943, publishes the most outstanding book or paper on the subject. The Foundation is an outgrowth of the permanent committee set up in Matamek in Canada after the first International Conference of Biological Cycles. Besides the award of a medal, the Foundation makes awards for outstanding work in each branch of science. Further information can be obtained from Dr. Ellsworth Huntington, chairman of the Committee on Awards, Hendrie Hall, York University, New Haven, Conn.

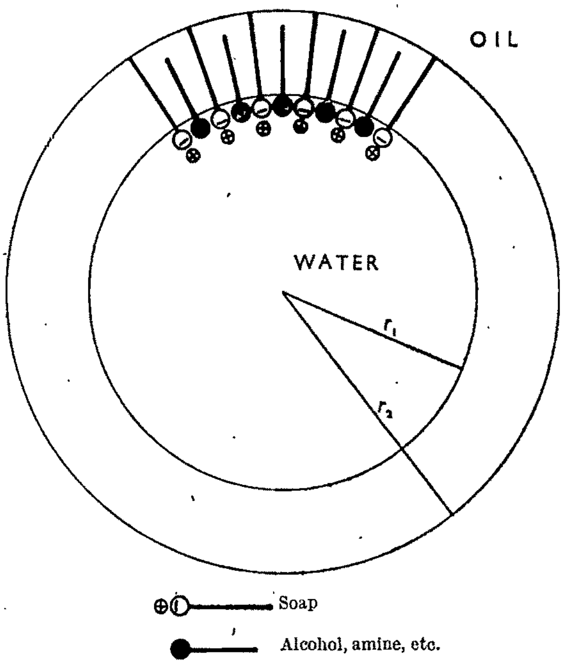
The INDEX to VOLUME 151 of "NATURE" (January to June 1943) will be published as a SUPPLEMENT to the issue for next week (JULY 31)

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Transparent Water-in-Oil Dispersions: the Oleopathic Hydro-Micelle

It is well known that oil – alkali-metal soap (or cationic soap, such as cetyl trimethyl ammonium bromide) – water systems of certain concentrations exist as transparent, electrically non-conducting dispersions, in which the oil is the continuous phase. Dilution of these systems with excess water inverts them to oil-in-water emulsions which are milky for low soap/oil ratios and transparent for sufficiently high soap/oil ratios. The transparent oil-continuous systems are familiar as 'soluble-oil' and similar concentrates: the essential conditions for their formation are (1) high soap/water ratio, (2) the presence of an alcohol, fatty acid, amine or other non-ionized amphipathic substance in mol-fraction approximately equal to that of the soap.



We believe that the properties of these systems and the conditions for their formation may be explained as follows. The disperse phase consists of sub-microscopic micelles having a core of soap-in-water solution and a surface monolayer of soap ion-pairs interspersed with non-ionized amphipathic molecules, with the hydrocarbon portions orientated outwards (see diagram). The high soap/water ratio ensures that the soap is undissociated; the presence of the water/oil interface containing orientated non-ionized amphipathic molecules allows undissociated soap ion-pairs to orientate there also, as an alternative to association in curd fibres; the non-ionized amphipathic molecules separate the soap ion-pairs sufficiently to prevent the repulsion between them that would otherwise occur, and indeed convert the repulsion in the monolayer into an attraction by forming complexes with the soap, similar to those describe elsewhere[1].

Semi-quantitative evidence can be offered in support of this hypothesis. We find, for example, tha transparent oil-continuous dispersions of the following approximate composition are quite stable, showing, however, a slight Tyndall effect:

Oil	150 parts by volume.
Water	100 „ „ „
Soap	50 „ „ „
Alcohol	40 „ „ „

If we take all densities as 1, the number of micelle containing 100 gm. of water as n, the molecula weight of the soap as 300, and the number of soa and alcohol molecules per cm.[2] of interface a $2\cdot5 \times 10^{14}$ each, we have for spherical micelles wit the radii indicated in the diagram (neglecting any soap in the bulk of the water),

$$\text{Volume of water} = \tfrac{4}{3}\pi r_1^3 n = 100;$$

$$\text{Volume of soap} + \text{alcohol} = \tfrac{4}{3}\pi(r_2^3 - r_1^3)n = 90$$
whence $r_2 = 1\cdot24\, r_1$.

Also area of water/oil interface $= 4\pi r_1^2 n$,

and hence

$$r_1 = \frac{3\ (\text{volume of water})}{\text{area of water/oil interface}} =$$

$$3 \times 100 \Big/ \frac{50 \times 6 \times 10^{23}}{300 \times 2\cdot5 \times 10^{14}} \text{ cm.} = 75\text{ A.}$$

Thus $r_2 = 93$ A., while $r_2 - r_1 = 18$ A. (compare the vertical depth of a soap monolayer, 20 A.). The micelle is therefore about 200 A. in diameter, which accords well with the optical properties of the dispersion.

A similar calculation for the transparent composition[2]

Oil	150 parts by volume
Water	100 „ „ „
Soap	100 „ „ „
Amyl alcohol	100 „ „ „
Mixed cresols	60 „ „ „

which shows scarcely any Tyndall effect, gives $r_2 = 1\cdot53\, r_1$, and by making reasonable assumptions of the depth of the monolayer we may deduce the micelle diameter as about 120 A., again in good agreement with the optical properties.

Gradual addition of water to the transparent oil-continuous system results first in the formation of an opaque emulsion, which with rather more water becomes viscous, though still non-conducting; evidently the micelles have to swell to accommodate more water, giving opacity, and then to deform owing to mutual contact, giving viscosity (addition of more *oil* to this viscous emulsion removes the viscosity but does not restore transparency, as would be expected). This spontaneous emulsification of the added water is made possible by the very low interfacial tension. Still more water inverts the system to a stable oil-in-water dispersion, because the lowered soap/water ratio permits the dissociation of the soap ion-pairs, giving the charged interface that favours ordinary hydrophilic micelles or globules[3].

We hope to extend this work by quantitative measurements on the simplest possible systems. Meanwhile, the conception of the 'inverted' micelle seems to us to be sufficiently well established qualitatively to merit description. It is the water-in-oil analogue of the hydrophilic 'swollen' soap ionic micelle, containing enclosed oil, described by Lawrence[4]; and since it contains enclosed water, and is tolerated by (though not attracted by) an oily dispersion medium, it may conveniently be termed the 'oleopathic hydro-micelle'.

Dual Decay of Potassium

It has been known for some time that the β-ray activity shown by potassium is due entirely to the isotope ^{40}K, which thereby transforms to ^{40}Ca. One might expect that ^{40}K would exhibit a dual decay, transforming to ^{40}A either by emission of a positron or by the electron-capture process. Attempts have been made at various times to detect positrons in the radiation from potassium but without success. These experiments, however, would not have detected the electron-capture process. In 1937, von Weizsäcker pointed out that considerations of the abundance of the chemical elements suggested that the isotope ^{40}K may in fact transform by a capture process to ^{40}A. The argument was as follows. The abundance of the chemical elements varies on the whole smoothly with atomic number, and the inert gases as a class show the same variation, except that they are rarer by several powers of 10 than their neighbouring elements. Argon is a striking exception, for it is about 1,000 times more abundant than would be expected from the general rule. The excess is due entirely to ^{40}A, and argon would obey the rule if the ^{40}A atoms could be attributed entirely to the transformation of ^{40}K.

Some time ago, at the suggestion of the late Dr. Harold Walke, we examined the radiation from potassium for evidence of the K-capture process, by placing a tray containing a layer of potassium salt in a large expansion chamber.

When an electron of the K-shell is captured by the nucleus, its place must be taken almost immediately by an electron from an outer shell, with the emission of a quantum of characteristic K-radiation. In the present case, the quantum will be emitted by an argon nucleus and its energy will be rather less than 4,000 electron volts. Practically all the radiation escaping from the layer of potassium salt into the air of the chamber will be absorbed within a few centimetres of the source. The absorption of each quantum gives rise to a photo-electron of about 0·5 mm. range, appearing in the cloud chamber as a large spot, easy to distinguish from any background cloud which may be present. The expansion chamber thus affords a sensitive method for the detection of the capture process, provided that the β-rays from the source of potassium salt are bent away by a strong magnetic field so as not to interfere with the observation of the spots.

In the course of the experiments 172 photographs were taken, some using layers of potassium chloride and some potassium nitrate; on these, twenty-eight large spots were observed, nearly all within 3–4 cm. of the source. There is good reason to believe that these spots are not a background effect of the chamber, for 117 photographs, taken under similar conditions except that layers of sodium salts were used, showed only two spots; while fifty photographs with no source gave no spots. The results show therefore that potassium emits an X-radiation of about the expected quantum energy, but it must be borne in mind that this radiation might arise from other processes than the K-capture process; as, for example, by the ionization of the K-level of potassium by the β-radiation. Calculation indicates, however, that these other effects are far too weak to account for the observations, and there seems to be little doubt that the K-radiation arises from the electron capture process

$$^{40}\text{K} \rightarrow {}^{40}\text{A}.$$

An estimate has been made of the probability of this process relative to the known β-transformation to ^{40}Ca. Owing to the great absorption of the K-radiation in the layer of salt and the uncertainty of the absorption coefficient, the calculations are very rough. They lead to the conclusion that the branching ratio is about three or four disintegrations by electron capture to one by electron emission, whereas von Weizsäcker estimated the ratio to be 1 to 3. As both estimates are liable to large errors, the discrepancy cannot be regarded as serious.

Recalculating the half-value period of ^{40}K to take account of this alternative mode of decay, we arrive at a value of about 4×10^8 years, not an unreasonable figure.

It would be interesting to be able to show that old potassium minerals, for example, granites or potassium feldspars, contain argon in amount corresponding to their age and potassium content. There exists already evidence of the presence of argon in granites[1] but its significance is not clear, for it is difficult to exclude completely the possibility of atmospheric contamination. The outbreak of war and the pressure of other interests prevented us from pursuing this aspect of the problem, and there seems little prospect of our being able to take it up for some time. For this and other reasons we make known our results, although not as complete as we would wish, without further delay.

Nature of Tetraploidy in Cultivated European Potatoes

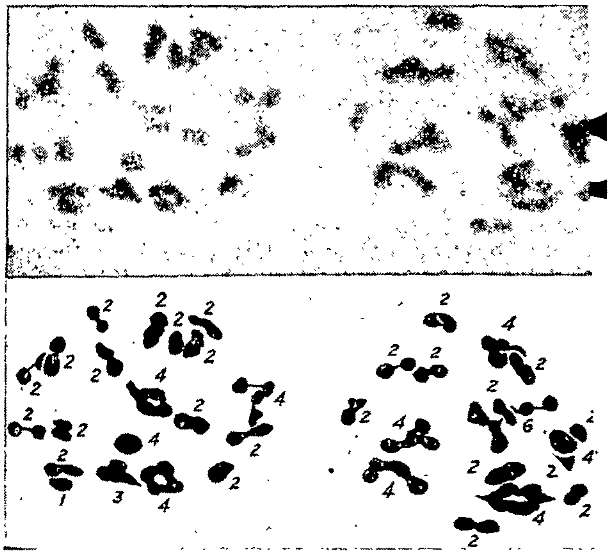
It must be unusual to find that the essential details of the genetic behaviour of an economic crop of such standing as the potato can still offer fertile grounds for controversy. Yet such is indeed the case.

The relevant facts of the cytogenetic situation are briefly these. The family Solanaceæ, to which the potato belongs, appears to be characteristically polyploid on the basic number 12, $2n = 24$ being the lowest chromosome number actually found. The European cultivated potatoes with 48 somatic chromosomes might therefore be suspected of being tetraploids. The published data on meiosis are, however, insufficient to establish the nature of tetraploidy. Although quadrivalents have been seen by Stow[1], Meurman and Rancken[2] and Ellison[3], there is no precise information on the frequency of their occurrence. In the genetic literature, on the other hand, two opposing views are to be found. The earlier workers, for example, Salaman[4], and more recently Black[5] and Collins[6], regarded the plants as functional diploids. The genetical possibilities of tetraploidy, though perhaps appreciated by K. O. Müller[7] in 1930 and by Asseyeva and Nikolaeva[8] in 1935, were not fully considered until 1937[9], a decade after the publication of the initial cytological facts just outlined. To this situation must be added a further complication in the shape of speculations on the true basic number of the solanaceous polyploid series. Assuming this to be 6 and not 12, allo-octoploidy has been proposed[3] though not as yet employed as a working hypothesis for potato genetics.

The choice essentially lies between a disomic and a tetrasomic interpretation of inheritance in this plant. Data which would critically distinguish between these alternatives are not yet fully available, but there is a growing weight of evidence in favour of tetrasomy. Thus some genetical work recently published[10] has shown a tetrasomic segregation of the dominant allele of the gene *nx* controlling a lethally necrotic reaction to infection with virus X. Further, from certain consistent deviations in these segregations it was concluded that the four *nx*-carrying chromosomes must, in a proportion of cases, pair and exchange partners and must therefore be homologous. This was suggestive of autopolyploidy, and the prediction was made that inspection of meiosis would reveal a comparable frequency of quadrivalent formation. The confirmation of this prediction which is now to hand is the reason for publishing this note.

	Multivalents per Cell													Total Cells
No of Multivalents	0	1	2	3	4	5	6	7	8	9	10	11	12	
No. of Cells	1?	—	4	5	13	15	15	11	4	2	—	—	—	70

The accompanying table contains the numerical data for the occurrence of multivalent groups in the pollen-mother-cells of the variety Flourball, obtained after fixation in acetic alcohol and staining by the Feulgen technique. Multivalents include trivalents, quadrivalents and a small number of groups of higher valency which will be referred to again below; the great majority are, however, quadrivalents. Variation in the proportions of multivalents is considerable, but about half the chromosomes present are generally involved. This is the case in the two cells figured, one of which has five multivalents, the other having six. The probable analysis of these cells may be made with the help of the labelled diagram. The two extreme cases listed with 9 multivalents are, however, the most instructive from the point of view of chromosome homology. One of these contained 8 quadrivalents and 1 trivalent and univalent; the other, 7 quadrivalents and 2 trivalents and univalents. Since the ability to form a quadrivalent must always denote a measure of homology between the four chromosomes involved, it would appear that at least 8 chromosomes are present in quadruplicate. This is a sufficiently high proportion of the possible maximum of 12 quadrivalents to be strongly suggestive of autopolyploidy on cytological grounds alone.



a *b*

Upper, photomicrograph of 2 pollen mother cells at late diakinesis from the variety Flourball from a permanent mount after Feulgen staining (× 1500). Lower, diagram showing probable analysis of configurations.

Quadrivalents have been seen in incompletely analysable material of at least four other varieties of potato dealt with in my earlier communication.

With regard to the groups of higher valency than four, one of these was encountered in each of eight cells, three of which showed a pentavalent, five a hexavalent and two an octovalent; a ninth cell showed two pentavalents. A hexavalent is visible in the accompanying figure (*b*). These cells represent only a small proportion of those analysed and they are best interpreted as signs of segmental interchange between two non-homologous chromosomes. Examples of similar multivalents ranging from penta- to octovalents are described in other potato varieties by Meurman and Rancken[2] and Ellison[3]. A minor amount of structural hybridity of this kind is not unexpected in a plant in which vegetative propagation predominates. Apart from this both cytological and genetical evidence agree in assigning autopolyploidy to the European potatoes. The likelihood of their hybrid origin in the genetical sense is, however, not thereby excluded.

I am indebted to the Agricultural Research Council for the provision of optical equipment and to Dr. I. Manton for help and advice.

Vitamin B_1, Vitamin B_6 and Biotin as Growth Substances for some Ascomycetes

IN continuation of earlier published investigations[1] on the significance of vitamin B_1 (aneurin, thiamin) and biotin (vitamin H) for the growth of different fungi, the need for growth substances of a number of Ascomycetes has been more closely studied. Leaving aside yeast-fungi, only relatively few of these have been more thoroughly examined in this respect[2].

The genus Ophiostoma (Ceratostomella) was found to include species with the most varying need of accessory growth substances. All the nine species examined required one or several growth substances to grow on synthetic media.

TABLE 1. THE EFFECT OF DIFFERENT GROWTH SUBSTANCES ON 9 SPECIES OF OPHIOSTOMA IN SYNTHETIC MEDIUM. (Bn = BIOTIN METHYL ESTER, Pyr = PYRIMIDINE, Thi = THIAZOLE.)

Species tested	Effective growth substances	
	Indispensable for growth	Growth-stimulating but not indispensable
O. piceæ	B_1 (Pyr)	—
O. stenoceras	B_1 (Pyr)	Bn
O. coeruleum	B_1 (Pyr)	B_6, Bn
O. quercus	B_1 (Pyr)	B_6, Bn
O. pini	B_1 (Pyr), Bn	B_1 (Thi)
O. ulmi	B_6	B_1 (Pyr ?)
O. fagi	B_6	Bn
O. piliferum	B_6	Bn
O. multiannulatum	B_1 (Pyr + Thi), B_6	—

The significance of vitamin B_6 (adermin, pyridoxin) is noteworthy for several of the examined species; at least six species reacted positively on an addition of this growth substance, and a closer examination showed that four of these had no, or in any case insufficient for growth, ability to synthesize vitamin B_6. One species, *O. multiannulatum*, required B_1 besides B_6. The table shows, furthermore, that B_1-heterotrophy occurred within a number of species; in one particular case, *O. pini*, combined with biotin-heterotrophy. Generally there was no need to add the entire B_1-molecule; supplied with only pyrimidine (2-methyl-4-amino-5-aminomethyl-pyrimidine hydrochloride) the organism itself was able to produce for the synthesis of vitamin B_1 the necessary thiazole.

Successful experiments to effect 'artificial symbiosis' proved that it was a question in these cases of a more or less complete loss of synthetic ability. Two species—no matter which two—one requiring B_1 (but producing B_6), the other requiring B_6 (but producing B_1), could consequently grow together on a substratum without addition of growth substances.

The weakest concentration of vitamin B_6 which exercised an observable effect was about 10^{-10}; it was nearly the same as earlier established, being valid for vitamin B_1 and biotin for those fungi reacting to these growth substances. An especially favourable bject for studies of the quantitative effect of B_6 proved to be *O. multiannulatum*. This fungus with the addition of suboptimal quantities of B_6 to a nutrient solution, otherwise optimal, produced quantities of mycelium, which, within certain limitations, were directly proportional to the added B_6-quantities. The same holds good also for *O. ulmi*, which, howver, showed a certain lability in regard to the B_6-heterotrophy.) The mycel./B_6-quotient thus obtained was of the same magnitude—about 500,000—as the earlier ascertained mycel./B_1-quotient of other fungi. Therefore with *O. multiannulatum* as test-object, it should be possible to carry out quantitative B_6-determinations in roughly the same manner as is employed with the B_1-determinations by means of Schopfer's Phycomyces-test[3].

Other ascomycetes which have here been examined have generally proved to be auxo-autotrophic or B_1-heterotrophic. Besides earlier known representatives of the latter type, *Discula pinicola* and *Diaporthe detrusa* may be mentioned here.

From certain points of view *Mitrula paludosa* is an interesting example of a fungus requiring biotin. Already it has been shown that biotin is a necessary factor for germination of the spores. For good growth in a synthetic medium vitamin B_1 also is required. The need of biotin for growth seems, however, in a peculiar way to be connected with the source of nitrogen; for example, *M. paludosa* with NH_4-nitrogen is unable to grow without the addition of biotin, while the fungus in question, on the other hand, grows quite well without biotin with NO_3-nitrogen, especially if the substratum is relatively acid.

A detailed account will be published in *Symbolæ Botanicæ Upsalienses.*

Breakdown of Paraffin Wax by Bacteria: A Source of Error in Corrosion Tests

IN work carried out by the British Non-Ferrous Metals Research Association on the corrosion of metals by domestic waters, glassware used for sampling water and for carrying out corrosion tests was coated with paraffin wax to prevent pick-up of alkali silicates. Tests carried out in waxed containers, or with water conveyed in them, gave inconsistent and non-reproducible results. It was observed from time to time that the wax coatings of some of the carboys were attacked and gradually disintegrated. In view of our previous experience of bacteria in altering the corrosive properties of waters, the possibility of bacterial action was considered.

Water from a carboy showing disintegration of the wax was inoculated into a sterile nutrient solution[1] containing no other source of carbon than flakes of the paraffin wax, and incubated at 30° C. After a few days a growth of bacteria was obtained which was attacking the wax. The species of organism responsible for the fermentation was not fully worked out, but it was found to be a coccus and possibly was a strain of the *Micrococcus paraffinæ* cited by Söhngen[2], who states that these bacteria are aerobic, of soil origin, and are commonly found in surface waters.

Bacterial activity in any water is bound to change its characteristics, and one of the variations investigated was the effect of this bacterial action on the apparent free carbon dioxide content of waters stored in waxed containers. A series of waxed and stoppered Winchester bottles, each partially filled with tap water and inoculated with cultures of bacteria known to attack the wax, was set up. Free carbon dioxide determinations were then made on the water in the Winchesters*. The interval before the first determination was made varied with each bottle, and the bottles were re-stoppered between each measurement.

For comparative purposes two unwaxed bottles containing the same water uninoculated were stoppered and tested over the same period.

The experiment showed that water in closed waxed containers contaminated with wax-attacking bacteria increased its free carbon dioxide content on storage as much as twenty times in forty days, whereas there was no change in the apparent free carbon dioxide content of the water in the two unwaxed bottles. It was possible to stop the activity of the bacteria by sterilization with heat or disinfectants.

It is known that the presence or absence of carbon dioxide in a water is a most important factor in determining its corrosive action, and the accompanying table illustrates the variation of corrosive attack which can occur if bacteria capable of attacking wax are present in a corrosion experiment where such a substance is used.

EFFECT OF WAX BACTERIA UPON CORROSION OF A DOMESTIC WATER IN METAL PIPES CLOSED AT BOTH ENDS WITH WAX.

Condition of water	Corrosion rate
Untreated water free from wax bacteria	0·9
Water inoculated with wax bacteria	4·1
Sterilized water	0·7
Sterilized water re-inoculated with wax bacteria	4·0

It is believed that other corrosion investigators may use paraffin wax in their work, and if this is so it is imperative that they should be on their guard against the action of these bacteria.

Although the observations have shown that the apparent free carbon dioxide content of a water may be increased by the action of certain bacteria on wax, it must be pointed out that many other microbiological processes normally occurring in natural waters are accompanied by a change in the carbon dioxide content of the water. We are therefore of the opinion that a correct assessment of the corrosive properties of a natural water cannot be made unless the biological state is taken into account. It is seldom safe to assume that any sample of natural water that has been stored for any length of time is representative of the water from which the sample was taken originally.

Library Stocks of Periodicals

AFTER this War, even more than after the Wa of 1914–18, learned and scientific libraries in Grea Britain will be faced with the problem of attempting to fill gaps in their sets of periodicals caused not only by the inability to obtain journals from enemy and enemy-occupied countries during the war-period, bu also by losses at sea and by destruction in air-raids As stocks in European countries may also have been destroyed in air-raids, there is likely to be a shortage in many cases, and in order to prevent an unseemly scramble on the part of individual libraries to ge volumes of which there may be an insufficient numbe of copies to go round, it is highly desirable that a representative and impartial body should decide, or a national scale, to which libraries the available copies should be allotted.

This allocation should form part of a much large scheme whereby the present holdings of learned periodicals in all important libraries in Great Britain would be surveyed and the needs of research in the various centres of learning assessed, due regard being had to existing subject specializations in variou institutions. Interchanges of stock could then be arranged so as to ensure the presence of complete sets of important publications in the libraries where they are most needed, and the elimination of many incomplete sets where they are little used. This may entail on the part of some libraries the sacrificing of treasured possessions, but it would be greatly to the benefit of research workers as a whole.

The obvious body to undertake responsibility for this work is the Library Association, which by its royal charter is entrusted, among other tasks, with promoting the better administration of libraries and encouraging bibliographical study and research. In practice, it will probably be found most economical for the actual work to be done at the National Central Library, where the machinery for this kind of undertaking already exists and would only need expanding Funds for this purpose would no doubt be forthcoming.

It may be mentioned that at least two such schemes in limited fields of knowledge, those of German studies and of medicine, were already being prepared before the War. The former, which was being undertaken by the Joint Standing Committee on Library Co-operation of the Association of University Teachers, had, I believe, reached the stage of recommending the transfer of stocks; the latter, a much larger undertaking under the auspices of the University and Research Section of the Library Association was only in the preliminary stage of making the survey of holdings, when it was interrupted by the War. Possibly a further extension of such specia subject-schemes might be the best way of tackling the job.

In any event, until the work has been done it would certainly seem premature for any fresh union catalogue of periodicals in British libraries to be undertaken, because its work would be so soon ou of date and therefore a waste of money.

RESEARCH ITEMS

zes of Virus Particles

THE estimation of size of ultra-visible virus par-cles presents many difficulties, and it was perhaps evitable that determinations by various workers sing different methods gave discordant results. An xhaustive and critical review of the whole question, y Roy Markham, Kenneth M. Smith and Douglas ea (*Parasitology*, 34, 315; November 1942), provides basis for the common interpretation of various ethods. Channels of approach to the determination f particle-size include ultra-violet light and electron icroscopy, X-ray diffraction, sedimentation and iffusion, filtration, and radiation inactivation, and ll are discussed in the present paper. The authors ecognize the great probability that viruses are often onsiderably hydrated, and particle-size would then e greater than in the dry state. One slight criticism ight be advanced—that very little notice is taken f the *p*H of the virus suspension. This would robably affect the size of protein virus particles, hich would be smallest at the iso-electric point. he literature on virus-sizes is condensed into three ables dealing with animal viruses, plant viruses and acteriophage. It is considered, however, that the agnitude of only three viruses can be stated with xactitude. Vaccinia virus is 235 mμ diameter in he hydrated state, and 200 mμ when not hydrated. he unhydrated virus of tomato bushy stunt averages 9·2 mμ in diameter, with molecular weight 10·65 × 0^6. Hydration increases these values to about 7 mμ for the diameter, and 18·8 ± 5·0 × 10^6 for olecular weight. Tobacco mosaic virus is rod-haped, 280 mμ × 15·2 mμ in the unhydrated con-ition, though it may aggregate to 532 × 15·2 mμ. ocumentation of the evidence shows a masterly horoughness, and the research worker in this field ill find the paper an invaluable summary.

iapause in the Eggs of a Grasshopper

IN considering cases of arrested development in insects it is logical to separate those directly due to environmental causes from those in which development is inhibited by some factor or factors internal to the organism. In the former case, normal development will be resumed as soon as the organism is returned to the right environment: in the latter case development continues to be inhibited even though the organism is experiencing apparently favourable temperature and humidity. H. E. Andrewartha discusses the phenomenon of diapause in the grasshopper *Austroicetes cruciata* Sauss. in South Australia (*Bull. Entomol. Res.*, 34, Pt. 2; 1943). It appears that this insect enters a state of diapause when in the embryo state only a few days after the egg has been laid. Diapause was eliminated from the eggs by exposing them to suitable low temperature (between 6° C. and 13° C.) for adequate periods when the embryo was at a suitable stage in development. If the exposure to low temperature was inadequate or inadequately timed, diapause was not eliminated. The influence of low temperature on diapause was due chiefly to changes which occurred in the yolk under the exposure. Yolk which had become modified in this way is stated to become suitable for the nourishment of the embryo and also allows it to move over the yolk during blastokinesis. Eggs exposed to a constant temperature of 16°–25° C. failed to develop fully: growth was slow and katatrepsis or re-orientation of the embryo as the result of movements during blastokinesis did not occur. Apparently this was due to the yolk being in an unsuitable condition to allow of the embryonic movement over the yolk surface. Prolonged exposure to 16°–25° C. (100–150 days) enabled the embryo to grow to a stage at which exposure to suitable low temperature eliminated the diapause. Intermittent exposure to 10° C. and 25° C. enabled the eggs to reach a similar stage of development.

Bacterial Growth

IN three papers by R. M. Lodge and C. N. Hinshelwood (*J. Chem. Soc.*, 208; 1943) the growth of *Bact. lactis aerogenes* in various media is described, with special attention to departures from the logarithmic growth curve. In a synthetic medium containing ammonium sulphate or amino-acids as the sole source of nitrogen, the results suggest that the maximum population is in part controlled by the formation of an inhibiting substance removable by cellular oxidation; that the earliest stages in the utilization of amino-acids is not usually rate-determining; and that the mutation involves a slight change in the delicate balance of these and other reactions. The lag between inoculation and the establishment of the logarithmic growth has been examined and is found to depend, among other things, on the age of the culture, and a lag-removing diffusible substance is produced by an actively growing culture. On storage for some months in a meat extract medium a strain of the bacterium showed in synthetic media an increased growth-rate, an increased stationary population, and a greater response to aeration. Variation could not be obtained in artificial media.

Coat Colour and Behaviour

C. E. KEELER (*J. Hered.*, 33, 371; 1943) has continued his investigation on the degree of tameness of varieties of the Norway rat. The F_2 of an albino carrying a black gene crossed with a wild grey rat was analysed by various tests for tameness. In 125 segregates it was found that the black-coated rats were less savage and more easily handled than their grey-coated sibs. It is believed that there is a pleiotropic effect of the gene for black-coat colour, in that the gene itself influences the temperament. It was found also that the gene for albinism has a profound dulling effect on the sense of smell.

Soil Moisture and Wilt Disease

IN the Niagara Peninsula in 1940 wilts due to *Verticillium albo-atrum* R. and B. occurred on a number of hosts, and Colin D. McKeen reports (*Canadian J. Res.*, March, 1943) the results of an extended series of investigations designed to ascertain the factors leading to such epidemic outbreaks, which occur only occasionally in the Peninsula. It is found that there is a very definite optimum temperature for the development of the pathogen in the soil and that an outbreak of disease is only to be expected when such soil temperatures coincide with the presence of relatively high values of soil moisture. This only occurs rarely in this locality, which thus usually escapes serious trouble from Verticillium wilt, because of the low soil moisture throughout that part of the growing period during which soil temperatures favour the growth of the fungus.

Almonds in Great Britain

A SHORT paper by H. Amphlett Williams (*J. Roy. Hort. Soc.*, 68, Pt. 3; March 1943) surveys the possibility of using almond nuts grown in Britain for human consumption during the present shortage. Nuts of *Prunus Amygdalus amara*, *P. A. Pollardii*, *P. tenella* (*P. nana*) and *P. Amygdalo-persica* contain dangerous quantities of hydrocyanic acid, but may be used in small quantities for flavouring, in the same way as bitter almonds. *P. Amygdalus* (*P. communis*) and its variety *praecox* produce about one twentieth of the hydrocyanic acid yielded by bitter almonds, and the nuts may be used in moderation for dessert and cooking purposes. Almond nuts from *P. A. macrocarpa* and *P. A. dulcis* make practically no hydrocyanic acid. It thus appears that the decorative almond trees (varieties of *Prunus Amygdalus*) in the neighbourhood of London could provide a welcome qualitative addition to war-time cookery.

Willows of Saskatchewan

IN the *Canadian Field Naturalist* (66, No. 7, Oct. 1942) there is an interesting paper "Notes on the Willows of Saskatchewan", by W. P. Fraser, emeritus professor of biology, University of Saskatchewan. The paper is based on collections and study made in the southern half of the province, and did not extend into the northern unsettled areas farther north than about the 54th parallel. The collectors co-operated in the exchange of specimens and notes, and this added to the interest and the amount of information obtained. It also resulted in the accumulation of a representative collection from this area in the herbarium of the University of Saskatchewan, and the present study is based upon them.

Synthesis of some α-Acyltetronic Acids

DERIVATIVES of α-acyltetronic acids are frequently found as products of mould metabolism, and the synthesis of such compounds is, therefore, of interest. Benary in 1909 obtained α-acetyltetronic acid in unspecified yield by condensing chloracetyl chloride with ethyl β-aminocrotonate in pyridine, cyclizing the resulting ester by heating, and deaminated the product by alkaline hydrolysis, obtaining α-acetyltetronic acid. Wilson Baker, K. D. Grice and A. B. A. Jansen (*J. Chem. Soc.*, 241; 1943) find that this acid is readily synthesized from β-anilinocrotonic ester and chloracetyl chloride. The methyl group of the acid is reactive and condenses with several aldehydes to form unsaturated compounds which can be reduced to the saturated α-acyltetronic acids. All the tetronic acids are very strong, the anion being stabilized by a resonance distribution of the charge between the oxygen atoms of the acidic hydroxyl group and the ester carbonyl group.

Solubility of Metals in Mercury

MOST metals dissolve slightly in mercury and they also react chemically with it to form intermetallic compounds. Platinum deteriorates slightly with age and becomes brittle with long exposure to it. Iron and tungsten seem inert, which may be due in part to the protection of adherent surface films of oxide, Lead, tin, zinc, and cadmium are sufficiently soluble to alter the properties of the mercury, which makes them unsuitable for use in contact with it in mechanical devices. According to an article by C. H. Prescott, jun. (*Bell Lab. Rec.*, 21, No. 4; Dec. 1942), the solubilities in mercury of silver, copper, nickel and platinum, and of iron and stainles steel, have been determined recently by the Be Laboratories by a new method employing a circulating still of 'Pyrex' glass. Mercury is evaporated fro a boiler into a condenser and then flows through bulb packed with scraps of the metal the solubilit of which is being determined, back into the boile The bulb which contains the metal sample is held i an oil thermostat at a temperature of 100° C. Sinc the mercury moves slowly, it becomes saturated wit metal which is precipitated in the boiler. Th solubility of silver was found to be 0·0018 gm./gm of mercury and that of copper was 0·00013 gm./gm The experiments on silver and copper were finishe in three and thirteen days respectively, which time correspond inversely to their solubilities. Nickel an platinum are so much less soluble that experiment on them required three and seven months respectively The solubility of nickel was $1 \cdot 4 \times 10^{-7}$ gm./gm and that of platinum was $4 \cdot 6 \times 10^{-9}$ gm./gm With iron and stainless steel, the boilers were perfectly clean after eight months. Solubility in mercury however, is only part of the story. The surfaces o silver, copper, nickel and platinum are easily wette and remain covered with a fluid film of mercury The material in equilibrium with mercury in thes experiments is, however, not the metal itself, but layer of solid amalgam. Actually, the metal mus be somewhat more soluble than the amalgam. Thu as it slowly dissolves, it is re-precipitated as a intermetallic compound which covers the surface an retards further attack.

Load Distribution between Interconnected Power Stations

IN a paper by Paul G. Kaufmann (*J. Inst. Elec Eng.*, 90, Part 2, No. 14; April 1943) on this subject the load distribution in a system of interconnecte generating stations is examined analytically wit the view of obtaining maximum system efficiency The author shows a graphical method of solving th general problem and discusses automatic load distribution, safety devices, and frequency control. A mathematical study of the problem is given in a appendix.

Notation of Elliptic Functions

IN a lecture to the London Mathematical Societ on June 17, Prof. E. H. Neville described an effectiv modification of notation in the theory of Jacobia elliptic functions. He replaces the classical symbol K, iK' for the quarter-periods by K_c, K_n, writes K_d for $-(K+iK')$, and attaches the symbol K_s to th origin. The result is to confer on the usual notation for the functions a structural significance; thus th function which, after Glaisher, is denoted by pq$u$ (where p, q are any two different letters chosen from s, c, d, n), is a function with a zero at K_p and a pole a K_q. General theorems and comprehensive formulæ now replace the sets of individual theorems and particular formulæ with which the subject has been overburdened. For example, the function pq$u$ has K_p+K_q for a half-period, and the identity K_s+K_c $+K_n+K_d=0$ exposes at a glance the classification of the twelve functions in terms of periodicity. Prof. Neville expressed the characteristic property of the Jacobian functions as a standardization of the lattice to which the functions are attached, and showed how from this point of view the general features of the fundamental transformations of Jacobi and Landen are obvious and the details are discoverable almost without calculation.

PHYSIOLOGICALLY ACTIVE FRACTIONS OF INDIAN HEMP

By B. C. BOSE and DR. B. MUKERJI

Biochemical Standardisation Laboratory, Government of India, Calcutta/Kasauli

IN spite of nearly fifty years of intensive study, the chemistry of hemp resin is still obscure. Earlier orkers reported that the active ingredient of Indian emp was not an alkaloid[1] but a resin[1,2] with oiling point 265° C. and a chemical composition epresented by $C_{18}H_{24}O_2$ ('crude cannabinol' of Cahn[8]). Wood, Spivey and Easterfield[3] showed that the high-boiling resin was a mixture of at least two comounds and isolated from it a pure crypto-phenol, *annabinol*, $C_{21}H_{26}O_2$, $d_D = -108°$, which formed a rystalline acetyl derivative, melting point 75° C. Later investigators[4,5,6,7] obtained apparently *contant boiling resins* to which they assigned the ormulæ $C_{21}H_{30}O_2$ or $C_{20}H_{30}O_2$. Work by Cahn[9] has onfirmed the findings of Wood, Spivey and Eastereld (*loc. cit.*). Myttenaere[10], on the other hand, elieves that cannabinol is not a pure entity but ontains several isomeric compounds, some of which re soluble in dilute alkalis, whereas others are nsoluble in them. The possibility of spontaneous onversion of the alkali-soluble compounds to alkali-nsoluble ones by heat or at room temperature has lso been suggested. The active constituents of ndian cannabis resin, according to the present state f our knowledge, are: (1) *cannabinol*[3,8], $C_{21}H_{26}O_2$, $_D = -108°$, which forms a crystalline acetyl erivative of melting point 75° C.; (2) *cannabol*[11], hich is isomeric with '*cannabidiol*'; (3) *cannabidiol*[12] ossibly in traces in Indian hemp), $C_{21}H_{30}O_2$, $(L)^{27} = -125°$, melting point 66–67° C., found in both gyptian and American hemp.

Very little systematic pharmacological work seems have been carried out on the various fractions btained from cannabis resin, and considerable eculation still exists as to which of the natural mponents isolated in a pure state is its characristic action due. Marshall[13] observed in 1897 that *nnabinol* (probably 'crude cannabinol', as pure nnabinol was isolated only in 1899) was physiogically active on human beings. Cahn[8], on the ther hand, reported that cannabinol, though toxic, as not the pharmacologically active component. ork, Bergel and Todd[14] leaned towards the same iew, in that they found the cannabinol-free resin to e the more potent physiologically. According to Adams *et al.*[12], *cannabidiol* is inactive. No report is available regarding the activity of 'cannabol' on laboratory animals or human beings.

The estimation of the narcotic potency of hemp drugs is important, particularly from the point of view of excise administration, and several chemical (Beam's test[15], vanillin test[16]) and physical (polarimetric test[17]) tests have been devised to measure this activity. However, none of these tests is considered satisfactory, as it is still open to question whether the tests measure the truly narcotic constituent of hemp resin.

An attempt was therefore made to study the pharmacological activity of various fractions of charas obtained from authentic Indian sources through the courtesy of Dr. H. B. Dunnicliff, director of the Central Revenues Control Laboratory.

1 gm. of charas was extracted in a Soxhlet extractor with 50–75 c.c. of carbon tetrachloride. The extract was shaken with 0·5 per cent sodium hydroxide solution. This was acidified and re-extracted with petroleum ether, the residue being taken up in every case with carbon tetrachloride. The following fractions were obtained: (1) carbon tetrachloride extract of genuine charas; (2) carbon tetrachloride extract of alkali-insoluble portion of charas; (3) carbon tetrachloride solution of alkali-soluble but petroleum-insoluble fraction of charas; (4) petroleum-ether extract of the alkali-soluble portion of charas.

EFFECT OF VARIOUS FRACTIONS OF HEMP RESIN IN CATS AFTER EVAPORATING THE SOLVENTS *in vacuo* AND TAKING UP THE RESIDUE WITH ALCOHOL.

Name of fraction	Principles likely to be present	Total number of experiments	Positive cannabis response Dose: c.c./kgm.	Onset of signs (hours)	Negative cannabis response Dose: c.c./kgm.	Absence of signs (hours)
CCl_4 extract of genuine charas.	All phenols—Cannabinol, Cannabidiol, Cannabol, etc.	26	1·61	1·75	—	—
CCl_4 extract of alkali-insoluble fraction of charas.	Cannabinol and some of its isomers ?	24	0·86	1·48	—	—
CCl_4 solution of alkali-soluble but petroleum-insoluble fraction of charas.	Some phenols excepting the alkali-insoluble portion of cannabinol.	30	—	—	2·96	3·40
Petroleum ether extract of the alkali-soluble fraction of charas.	*ibid.*	20	—	—	3·00	3·18

The well-known Gayer's test[18] was employed on cats for pharmacological evaluation. All the animals weighed between 2·0 to 3·0 kgm. and were kept in the laboratory for at least four days on laboratory diet before experiments were started. The animals were fasted overnight before the drug was given by means of a Ryle stomach tube. In the accompanying table, results obtained from nearly a hundred experiments have been included. These were collected from cats found sensitive to cannabis action, and the maintenance of the initial degree of responsiveness was continually checked by cross experiments and interpolation of initial effective dose of whole charas when no cannabis response was obtained with the alkali-soluble fractions. The drug was administered in a small volume of absolute alcohol having no effect on animals. The solvent was evaporated *in vacuo* because of the toxic effect of carbon tetrachloride on cats even in small doses. Positive cannabis response was indicated by initial excitement, followed by inco-ordination, rocking movements of the head, sluggish corneal reflex, somnolence, and mild narcosis.

It will be seen from the above that the alkali-insoluble fraction (containing cannabinol, etc. (?)) was found to be the pharmacologically active fraction under the conditions of our experiments. The alkali-soluble fractions even in three times higher dosage and in the same experimental conditions did not reveal any narcotic activity. This raises the question as to whether 'cannabinol' could be considered as a physiologically inactive phenol, as has been indicated in previous reports[8,13].

Unless further experimental work is done with pure cannabinol, it seems too premature to hazard any definite statement regarding its physiological potency. It may, however, be presumed from the biological assay results on the alkali-insoluble fraction of charas that possibly *cannabinol* may be the precursor of the true active ingredient, the phenol being broken down in the system to some other derivative possessing the ethenoid linkage but with more intense physiological activity. The synthesis by Adams and his co-workers[12] of some tetra-hydro-cannabinols possessing strong hashish activity also lends support to this supposition.

Our thanks are due to Sir R. N. Chopra and Dr. H. B. Dunnicliff for their continued interest in this work.

FISHERIES RESEARCH IN AUSTRALIA

VALUABLE research in biological fishery problems is being carried out by the Council for Scientific and Industrial Research, Commonwealth of Australia. The primary objective of the current investigation* is to obtain a well-founded estimate of the pelagic fishery resources of Australian waters, and in this is included oceanographical work concerned with changes in currents and water conditions generally, together with their effect on the amount and distribution of plankton. Roughly speaking, the course of the fisheries varies according to the ever-varying conditions of the sea. The report on the pelagic Tunicata is of importance as the members of this group serve as indicators of changing ocean graphical conditions which affect the course of t fishery.

This is the first report to be published on t investigations covering the period from May 1938 January 1941, carried out by the motor ves *Wareen*. During this period the whole south-ea Australian area was repeatedly traversed, a oceanographical observations were made as frequent as they could be without interfering with the mc specific fishery investigations. An intensive study h been made of the pelagic Tunicates which, except f Crustacea, form the chief portion of the zooplankto The Tunicates are much more abundant in the su tropical and tropical waters than in the great fishe area of the colder portions of the northern hemispher No species typical of sub-antarctic (cold wate influences are found, those present being main circumtropical and sub-tropical.

Comparison of species and their relative numbe with those of other regions indicates a much clos affinity with south Japanese and Philippine a Indo-Malayan than with Californian condition Here there is a distinct probability that the pelag fisheries of south-eastern Australia will develop west- rather than on east-Pacific lines. From t unusually large number of rare circumtropical a sub-tropical species in 1939–40 and from the simu taneous reduction in number of the more indigeno species, abnormally warm conditions apparently pr vailed during that period, along with a progressi decline in the volume of plankton from 1939 onwar —conditions which adversely affected the fisheries.

The plankton, including the Tunicata, is mu more concentrated in the upper 50–100-metre wat layers than at greater depths, and several times mo concentrated in the warmer than in the colder mont of the year. Lesser and more uniform concentratio occur at greater depths. This affords some explan tion of the surface shoaling of pelagic fishes a indicates that future investigations will yield mo reliable results and be most economically pursued chiefly inclined to the upper water layers in t warmer seasons of the year.

Of the pelagic salps of south-eastern Australi *Thalia democratica* is by far the most characteristi the next being *Ihlea magelhanica*, and thirdly *Sal fusiformis*. Among the Copelata the outstandi species is *Oikopleura longicaudata*. The young colonies of *Pyrosoma atlantica* are extremely abunda at times. A list of the species so far found in sout eastern Australian waters is given, but systemat and general data with keys to identification a reserved for a separate publication.

The study of the Australian mullet fishery relat chiefly to *Mugil dobula*, probably the most importa of the inshore species. The result of the work show there is undoubtedly over-fishing and that mo restrictions should be placed upon the operatives the industry in order that the stocks may be allowe to recover and possibly improve beyond earlier level A scheme for immediate and future action to secu restoration of the fishery is submitted.

The mullet fishery operates along almost the enti coast of Australia. There is a two-phase fishery *Mugil dobula* which spends the greater part of t year in rivers and lakes and a few months in movin in truly marine water in shoals along the coast spawning migrations. It is found by tagging exper ments that the river and lake fish are not, as t fishermen supposed, distinct from those in the se

* Commonwealth of Australia: Council for Scientific and Industrial Research. Bulletin No. 153: Pelagic Tunicates in the Plankton of Southeastern Australian Waters and their Place in Oceanographic Studies. By Dr. Harold Thompson; with a Statistical Analysis of Data on Total Plankton, by G. L. Kesteven. (Division of Fisheries, Report No. 8.) Pp. 56+1 plate. Bulletin No. 157: Studies in the Biology of Australian Mullet, 1: Account of the Fishery and Preliminary Statement of the Biology of *Mugil dobula* Gunther. By G. L. Kesteven. (Division of Fisheries, Report No. 9.) Pp. 147+2 plates. (Melbourne: Government Printer, 1942.)

but merely different phases of one life-history, the lake fish being slimy and dark and the sea fish clean and shining blue. On the east coast there is a continuous movement from the southern rivers into those north of them, and there must be recruitment from the north as there are apparently no separate races, and there is probably one intermingling stock. Thus the problem is one for a single uniform policy.

The mullet is a bottom feeder and eats the sandy and muddy slime of the fresh and brackish waters, taking in the organic substances in it. Presumably, feeding ceases when the fish move to the sea. The larval development is unknown, but there are reasons to believe that the egg is pelagic and hatches within a short period, spawning probably occurring at or near the mouths of the estuaries in the surf zone. The young fish are still within a few miles of the estuary at the end of the first year, but after that they move farther up the rivers or lakes and spend their second and third year there.

NEW ZEALAND EARTHQUAKES DURING 1941

ACCORDING to the report on seismology for the year ended December 31, 1941, which has recently been received from the acting director, R. C. Hayes, the total number of earthquakes reported felt in New Zealand during 1941 was 107, the smallest number in any year since 1928 (Dominion Observatory Bulletin No. R.27, extracted from the Annual Report of the Department of Scientific and Industrial Research, 1941–42, Dominion Observatory, Wellington, New Zealand). The earthquakes, in addition to being reported by numerous individuals as having been felt, were recorded by instruments as follow, the situation of the instrument being given first, and the type of instrument in parenthesis afterwards: Auckland (Milne-Shaw), Arapuni (Milne), Rotorua (Jaggar), Tuai (Wood-Anderson), New Plymouth (Wood-Anderson), Hastings (Jaggar), Bunnythorpe (Jaggar), Wellington Central Station (Galitzin-Wilip, Milne-Shaw, Wood-Anderson, Jones, Imamura), Takaka (Imamura), Greymouth (Jaggar), Christchurch (Galitzin three components, Wood-Anderson), and Monowai (Jaggar). Milne-Shaw seismograph No. 36 was installed at the Auckland Museum early in April. However, it was not until November that the necessary apparatus was obtained for maintaining accurate time. There was considerable delay in establishing a Wood-Anderson seismograph at Kaimata near Greymouth owing to the war, but some progress has been made. The public works officials at Rotorua have developed a method of obtaining records on blueprint paper instead of on smoked cardboard. The seismograph at Chatham Islands has been temporarily suspended owing to the War.

Of the 107 shocks in 1941, 61 were felt in some part of the North Island and 55 in some part of the South Island. Nine were felt in both Islands. The maximum intensity reported felt was Rossi-Forel (*R.F.*) 8. Although the number of shocks felt was small, seismograph records indicate that minor activity was much the same as in previous years. Earthquakes were comparatively frequent in the far north-eastern part of the North Island and in the central districts; and there was more activity than usual in Canterbury. On the other hand, most of Hawke's Bay was comparatively free from earthquakes. Occasional shocks originated in the far south-west. The only two outstanding seismic events occurred early in the year. These were (1) a shock of *R.F.*8 originating near Taneatua, in the Bay of Plenty, on January 9; and (2) one of *R.F.* 6–7 near Lake Coleridge, in Canterbury, on February 7. The Taneatua shock was of very shallow origin, and in spite of the high intensity in the epicentral region the maximum radius of the 'felt' area did not exceed 70 miles. The Lake Coleridge shock was of normal depth and its 'felt' area was also small (maximum radius about 100 miles). After-shocks of the Lake Coleridge disturbance continued at intervals throughout the remainder of the year. Both these earthquakes were approximately 5 on the instrumental magnitude scale. Other shocks with *R.F.* intensity 6 or greater than 6 were: April 6d. 18h. 46·8m. U.T. from Taumarunui and Hastings to Queenstown and Dunedin (6), May 29d. 11h. 17·1m. U.T. parts of southern Hawke's Bay (6+), August 10d. 10h. 05·2m. U.T. Southland, parts of Otago (6), and September 24d. 11h. 39·5m. U.T. Opotiki to Wanganui and Waipawa (6). Four further shocks had scale 5 or rather greater, and one had scale 3 intensity.

Two notable features of the 1941 results were: (1) a prevailing tendency for activity to be concentrated towards the north-western side of the general seismic region; and (2) the occurrence of shocks slightly deeper than normal in the submarine region between Taranaki and Nelson and beneath the northern part of the South Island. This has been confirmed by a recent revision of the earthquake records of previous years.

NUTRITION IN RELATION TO BONE GROWTH AND THE NERVOUS SYSTEM*

THE problem had its origin in observations made in 1918, when an experimental study of rickets was in progress. Some of the animals developed severe inco-ordination of movement, independently of rickets, and the condition clearly involved a different etiological factor. The latter differentiation of the anti-rachitic vitamin from vitamin A made it possible to show that the inco-ordination of movement in young animals was due to vitamin A deficiency.

Examination of the peripheral and central nervous system revealed widespread degeneration of afferent nerves (cranial and spinal) and ascending fibres in the central nervous system. The interpretation of the results at this period was that vitamin A deficiency produced degenerative changes in most nerve cells of afferent and ascending nerves, but left those of the descending and efferent nerves intact. Here the position was left for some years, but the unsatisfactory nature of the explanation impelled a return to the investigation. Since the 8th nerve was obviously particularly affected, serial sections of the labyrinthine capsules were studied. This examination led to the finding of abnormal bone growth in the internal auditory meatus, which was clearly pressing on both divisions of the 8th nerve. A similar overgrowth of periosteal bone was found to explain destruction of other peripheral afferent nerves. Many other abnormalities of the nervous system resulted from the same cause, including deformity of the cerebellum and medulla, increased intracranial pressure, internal hydrocephalus, reduction of the subarachnoid space and of the cerebrospinal fluid, and the squeezing of the whole of the central nervous system in its bony covering.

---

* Substance of the Croonian Lecture delivered by Sir Edward Mellanby, K.C.B., F.R.S., before the Royal Society on July 15.

The investigation had now come back to its starting point, namely, bone development, since it was obvious that the essential problem, although associated with such drastic nervous defects, was largely one of abnormal bone growth. In the absence of vitamin A and carotene, bone growth in certain positions was excessive. Whereas it was shown in the earlier work that the antirachitic vitamin (now vitamin D) controlled the hardening of bone, it was now evident that vitamin A restrained the bone cell elements in some way, so that in its absence there was loss of normal bone shape and also of co-ordination of its growth in relation to that of the enclosed central nervous system. Although many of the essential facts of the relation of vitamin A to bone morphogenesis are still unknown, some recent results on this problem were described.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, July 24

Institute of Physics (Midland Branch) (at the University, Edmund Street, Birmingham), at 2.30 p.m.—Lectures by Prof. R. Peierls and Dr. L. Jánossy on "The Meson".*

Wednesday, July 28

Zoological Society of London (in the Meeting Room, Regent's Park, London, N.W.8), at 3 p.m.—Sir John Graham Kerr, F.R.S.: "A Naturalist in the Gran Chaco, South America".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Master or Mistress to teach mainly General Science in the Junior Technical Schools, Bath Technical College—The Director of Education, Education Department, Guildhall, Bath (July 30).

Johnston Chair of Biochemistry—The Registrar, The University, Liverpool (July 31).

Lecturer in the Department of Chemistry—The Principal, Derby Technical College, Normanton Road, Derby (July 31).

Veterinary Inspectors (temporary) in the Ministry of Agriculture and Fisheries—The Ministry of Labour and National Service, Central (Technical and Scientific) Register (Reference No. ONF. 1399), Alexandra House, Kingsway, London, W.C.2 (August 2).

Demonstrator (male or female) in Anatomy—The Registrar, The University, Sheffield (August 2).

Speech Therapist—The Secretary to the Chesterfield and Mansfield Education Committees, Education Offices, Mansfield (August 3).

Head of the Building Department—The Registrar, Technical College, Sunderland (August 6).

Lecturer (man) in Science (Physics and Chemistry)—The Principal, Borough Road College, Isleworth, Middlesex.

Teacher of Engineering Workshop Practice in the Smethwick Junior Technical School—The Chief Education Officer, Education Offices, 215 High Street, Smethwick 41.

Science Master to teach mainly Biology in connexion with a Pre-Agricultural Course for Boys at the Maidstone Technical Institute—The District Secretary, Kent Education Committee, 13 Tonbridge Road, Maidstone.

Research Chemists, Physicists and Fuel Technologists for research and development work in connexion with the Ceramic Industry—The Director of Research, British Pottery Research Association, Queens Road, Penkhull, Stoke-on-Trent.

Lecturer in the Mathematics Department—The Principal, Heriot-Watt College, Edinburgh.

Visiting Lecturer in Psychology—Tne Secretary, King's College of Household and Social Science, c/o University College, Leicester.

RECONSTRUCTION OF LOCAL GOVERNMENT

IN the attention which is already being directed to the varied problems of reconstruction which we must be prepared to face in the post-war world, the significance of one fundamental group of problems which impinges on all the rest is rarely adequately stressed. Whether we are considering problems of social security and the means of implementing the proposals of the Beveridge Report, those of national health, of education, of the utilization of the land and its resources, or of trade and employment, the development or evolution of democratic institutions to serve the changing needs of our society is of critical importance. The nature and structure of the central government, its relations to local and representative institutions, the training and recruitment of the staff by which effect is to be given to the Government's policy, the place of scientific method and of the technical expert in the government machine—these are all aspects of the machinery of government which require careful study. In the light of that examination we can approach the central problem of developing a new society in which the essential measure of central planning is to be ensured while preserving the freedom of enterprise and the individual initiative and vigour which have been the secret of so much of the greatness of Great Britain in the past.

Attention is already being directed to a number of these problems by the Government. A committee of Ministers and an interdepartmental committee of permanent heads of departments is understood to be at work considering, *inter alia*, the machinery of government, and another committee has now been appointed under the chairmanship of the Financial Secretary to the Treasury to examine the general question of the training of Civil servants. Experience in civil defence and a succession of reports such as the Scott and Uthwatt Reports are enforcing reconsideration of the question of regionalism and the size of the local government units to make planning in war and in peace effective. While the democratic system of Great Britain implies the supremacy of a national government in which the interests of the parts are woven into the over-riding interests of the whole, central government cannot be successful or other than tyrannous unless the interests of the parts are maintained.

Few things show more clearly the weakness of the existing local government system of Great Britain than that it should now, after eleven years, be necessary to pass special legislation to bring under planning control "land which is not subject to a scheme or resolution under the Town and Planning Act of 1932". The duties of local authorities with regard to post-war planning will be vital and, if the main proposals of the Scott and Uthwatt Reports are enacted, will be such that they cannot avoid them. It is essential, therefore, that every effort should be made to ensure that the structure and machinery of local government is administratively sound and served with vigour and with vision—that it fulfils its vital function of bringing to the national machinery of government the local knowledge, the personal element and responsibility which are essential if our institutions are to remain democratic and representative as well as efficient.

The structure and reform of local government have now been considered in at least three reports. That of the General Purposes Committee of the Association of Municipal Corporations on the re-organization of local government was adopted by a general meeting of the Association in London, and its recommendations have now been submitted for consideration by Sir William Jowitt's Committee on Reconstruction. A report on the "Future of Local Government" has since been published by the Labour Party, while the National Association of Local Government Officers has issued, as an expert contribution to the problems of the future of local government, an interim report on the reform of local government structure prepared by an independent committee of local government officers. The general similarity both of the conclusions of these reports as to the weaknesses of the present system and of the recommendations for reform is very striking.

The Labour Party's report and those of the Association of Municipal Corporations and the National Association of Local Government Officers remark that there are too many local authorities in Great Britain, and that the majority are too small to tackle problems of post-war reconstruction. The standard of social services is very unequal; and an undesirable distinction between town and country is made by the present structure. The National Association of Local Government Officers also emphasizes the need for securing better co-operation between local government areas in such matters as education, medical services, milk supply, highways and libraries. Either the structure of local government must be drastically amended, or an undesirable degree of control by the central government will be necessary.

As a first step it is recommended that the Government should at once set up a Local Government Boundary Commission to survey the whole of England and Wales and recommend such changes in local government boundaries as are desirable. This Commission should be a permanent body and should be constituted the tribunal for the consideration of all matters affecting local government boundaries in the future.

The importance, in any change in local government, of fusing the interests of town and country so that within each major unit there is a well-balanced grouping, actual or potential, of diversified industry, agriculture, commerce and residence is recognized by the Association of Municipal Corporations, whereas it advocates that such services as gas, transport and electricity should be part of a national scheme under public ownership, with a proper locus for local authorities in regard to prices and services. The difference between these proposals and those of the National Association of Local Government Officers appears, in fact, to be superficial rather than fundamental, and although the Labour Party's report does not specify in detail the size or area of the units to be adopted, it appears improbable that they would differ significantly from those of the all-purpose authorities advocated by the other reports.

These three reports agree in making an attempt to meet that need for greater opportunities for personal contacts between all grades of society, and machinery for fuller exchange of views and interests between them which are such important factors in the method of discussion that is the essence of a democratic system. The importance of the personal factor cannot well be overstressed. The contacts established through the War have already had a loosening and educating influence on the social structure, and we must look to this process to overcome the opposition to change as such which has already manifested itself, even in the Association of Municipal Corporations, particularly on the part of the small units which fear the loss of either power or individuality.

Two points are of fundamental importance. To the local authority we must look in large measure for the redress of the balance against any bureaucratic tendencies which may be inherent in the large-scale measures of planning which are as inevitable in post-war reconstruction as in the development of our full war effort. That objective can only be secured when we are able to obtain the services of the right type of men and women for the local authorities. The very best and not the mediocre, indifferent or self-seeker must be attracted to the local councils, and any obstacles to such enlistment must be removed as fully as possible. Local government authorities must be given the dignity and status to make that appeal. They must also prove that they deserve such dignity and status by the vision, the wisdom and the magnanimity with which they address themselves to the problems confronting them. Independence of mind, sound and disinterested judgment, rather than party allegiance, must be the hallmark of the local councillor if our democracy is to preserve its vital character and serve the new age.

The solution of that problem may well offer some assistance in the solution of a further problem, as important in local government as in the national sphere—that of the place of the scientific or technical expert. The problem is in some respects not dissimilar from that of the control of industry and of its relations to the State, and the fundamental thinking and inquiry which offer a solution to the one problem may well be found to have a profound bearing on the other two.

It is at this point that Prof. Ernest Barker's great work, "Reflections on Government", renders such valuable service. Unless we clearly understand what is involved in a democratic system, the way in which government depends on the mutual exchange of ideas, on mutual criticism of the ideas exchanged, and on the common and agreed choice of the idea which emerges from the ordeal of interchange and criticism, we may well advance proposals which destroy the essential balance of forces and the spiritual quality of the processes on which the democratic system depends. That danger is patent from the most cursory reading of the numerous proposals for reconstruction which have been advanced by industrial organizations, trade associations, and Chambers of Commerce, the Unilever paper "The Problem of Unemployment" being a conspicuous exception; and it cannot seriously be maintained that professional associations, albeit unconsciously, are likely to be free from fault in this respect.

It is the besetting danger of professional associations that such organization tends in time to become conservative and directed towards self-preservation rather than seeking the public good, no matter how gradual the stages by which the initial pioneering and reforming spirit is sloughed off. Against that danger professional men can and should be on their guard, and the report of the National Association of Local Government Officers, like that of the Institution of Municipal and County Engineers on Post-War Planning and Reconstruction and the earlier report of a joint committee of local sections of the Society of Chemical Industry, the Royal Institute of Chemistry and the Chemical Society to the District Commissioners for Depressed Areas in 1935, is an admirable example of the way professional associations do in practice make valuable corporate contributions to the discussion of public affairs. That difficulty is inherent in the nature of a professional association, and even from the point of view of the advancement of professional knowledge, one of the major problems is to secure that the governing body or council is sufficiently receptive and responsive to new ideas, while preserving the standards and tradition of the profession.

There is, however, a second difficulty which is important. Dr. Barker's analysis here deserves the careful consideration of the scientific worker. Within his sphere the expert has clearly the duty, as well as the right, to speak. Information, however authoritative in regard to any particular field, must, as Dr. Barker points out, necessarily be compared with, and adjusted to, information in regard to other fields. There is no issue in politics which falls within one field and one only. A like proposition might be advanced of industry. It is only in the procedure of science that particular fields are abstracted and isolated for inquiry. Moreover, information furnished by the expert in regard to his field, or by a number of different experts in regard to their different fields, is information which touches only the actual body of knowledge in the field or fields concerned. By its nature it is confined, on the whole and in the main, to measurable data. It cannot solve and is not intended to solve the problems of action, though it may set limits to action, and in that sense and to that extent determine action.

We must therefore recognize that, as Dr. Barker rightly insists, the solution of the problems of action in social and political life depends on more than scientific measurement and the results of such measurement. It depends also on the process by which different claims of right and acknowledgments of duty, which must be made sufficiently commensurable to be adjusted to one another, are set to give information about themselves, and in so doing, to reconcile themselves to one another in the certainty of a uniform and accepted law. The services of the scientific expert, as such, are thus limited to advice on the limits of action or the measurable factors involved in action, not on the action or on policy itself.

For this reason the conception of a planned State managed by experts in the art of production is alien to the mental assumptions and preconceptions on which the life of the modern State has come to proceed. For the same reason, the idea of self-government of industry is an illusion to be firmly rejected, as Mr. Herbert Morrison indicates, though not entirely for his reasons. A much closer integration of industry with the structure of society is required and, as Dr. Barker points out, and as C. E. Purdom illustrated in his suggestive book "The New Order", the solution to the problem of the relations of business and professional enterprise to the State may lie rather in the adoption, not by the State of the methods of business and industry, but by business of the methods of open discussion and voluntary agreement which have been so highly developed in the State.

The importance of regionalism in this connexion is the possibility it offers, as developments during the War have shown, of tapping more effectively the immense reserve of devoted service, initiative and capacity of leadership which had not previously been enlisted by the organs of local government and which for various reasons is unlikely to find an outlet in national politics. To utilize this material, larger units and wider powers and responsibilities in local government are essential, and a machinery in which sound administrative principles are embodied with the flexibility and adaptability required to serve the changing needs of the times. Secondly, and equally important, by integrating at the local and regional level the knowledge and services of the professional or scientific expert, it should assist in that important work of educating not only the electorate but also the councillors and others who are called upon to act on the recommendations of expert commissions in special fields.

Dr. Barker makes the point that there is a profound sense in which the process of democracy is itself scientific, and the method of procedure by inquiry, whether by Royal Commission as the Barlow Commission, or special committee as the Scott and Uthwatt Committees, is essentially scientific. Procedure by genuine discussion, starting from an adequate knowledge of the relevant facts, and proceeding, by an adequate assessment of the significance of the different data, to action based on that knowledge, bringing one claim of right into argument with another, and eliciting acknowledgments of duty to meet and face claims of right, inducing men to make for themselves compromises between different claims, and to achieve for themselves a union and a correspondence between rights claimed and duties acknowledged—this is true not only to the ideal of democracy but also to that of scientific government. The reason why, when strengthening the general method by adding the particular machinery of expert scientific commissions, the results have been disappointing, is that we have failed to carry the process of integration and discussion to low enough levels. We have not met sufficiently fully the intensely searching demands which the complex problems of to-day make not only on the machinery of government but also on the men responsible for running the machine and the ordinary citizens whose interests it is designed to serve.

This problem of education is, in fact, the key problem. Until it is met, and the allied problem of improving the machinery of discussion at all levels, we cannot secure the essential integration and the balance which the efficient functioning of a democratic system requires. Without it the adjustment of economic claims and counter-claims, for example, can only be very imperfectly achieved at a stage preceding action by the State. The self-discipline and self-planning which are as important as State planning and State discipline also depend on an educated order, and if Dr. Barker is right in holding that the expert bodies in industry and economics or in other special fields should be advisory and consultative, they can only function efficiently when this condition is fulfilled.

Planning in a democracy is necessary, but it must be compatible with the liberty of a general society of free minds. In ensuring that condition, local government has a vital part to play. The proposals advanced in these reports for strengthening local government to meet the new conditions have a strong claim on the interest of scientific men, who should be stimulated to take their full share individually in such work, and individually and collectively in the thinking that has yet to be done to modify or strengthen our political institutions where needed to ensure that in the new order the essential human freedoms are served with all the knowledge and experience which science can bring to bear.

TIME BASE CIRCUITS

Time Bases (Scanning Generators)

Their Design and Development; with Notes on the Cathode Ray Tube. By O. S. Puckle. Pp. xii+204+5 plates. (London: Chapman and Hall, Ltd., 1943.) 16*s*. net.

THE cathode-ray tube has found its chief application, in the hands of the research worker, in connexion with the study of the time-variation of voltages and currents. In such applications, the quantity under observation produces a deflexion of the spot on the screen of the tube, usually in a vertical direction, while the application of a steadily changing voltage makes the spot move in a perpendicular direction. The resultant movement of the spot traces out a Cartesian graph of the variation with time of the quantity being studied.

The circuits producing the steadily changing voltage which makes the spot execute the 'time-axis' or 'time base' have been called 'time base circuits' or, more shortly, 'time bases'.

The book under review deals with the design and properties of circuits which have been developed, both for this purpose and for the similar object o making the spot traverse or *scan* the screen of th cathode ray tube in connexion with television. I the latter application the circuits are sometime called scanning generators—the name adopted as part of the title of the book.

The requirements of these two applications diffe only in that, in the case of the television circuits stress is laid on simplicity coupled with a speed o traverse the irregularities of which are inappreciabl to the viewer, whereas in the 'research' circuits simplicity is not so important.

The majority of time-bases depend on the exponential rate of charge or discharge of a condense which is in series with a resistance and a source o electromotive force, the periodic charge (producing the working stroke of the traverse) and discharge (producing the fly-back) being effected by an electronic switch or 'trigger circuit', which is usually a type of 'relaxation oscillator'. The action of the trigger circuit is often initiated by a 'synchronizing' or 'locking' impulse in order that the time base may start at a desired instant. The output from the time base circuit may not be sufficiently linear, that is, the speed of movement of the spot may not be sufficiently constant. To cure this defect 'linearizing' circuits are added. Further, the output may be insufficient in amplitude or unsuitable in form, and may cause aberrations in the trace on the cathode ray tube. Properly designed amplifier stages may be used to overcome these troubles.

Information on the design of time bases is scattered throughout reports on electrical, medical and other research, being often mentioned in passing, as a detail of the equipment used, and therefore difficult to find. The author has performed a very useful service in collecting, in one book, a large amount of material on time bases (accompanied by clear exposition and by criticism), to which he has added some account of his own work in certain aspects of the subject.

Some idea of the scope of the book may be gained from the following summary.

After classifying the different types of time base the author shortly disposes of the simple time bases produced by a sinusoidal source and devotes the rest of the book to the (ideally) 'linear' time base, in which the velocity of the spot is constant. As mentioned above, the movement of the spot is usually caused by an exponential voltage charge. The author, in a chapter entitled "Linearization of the Trace", describes certain artifices which make the rate of movement of the spot more constant. This chapter is prefaced by a discussion and definition of linearity, and includes an ingenious circuit in which feed-back increases the degree of linearity to an extent equal to the stage-gain of the valve. A chapter devoted to trigger circuits which control the operation of the time base condenser describes circuits such as the transitron, 'flip-flop', and Schmitt's trigger circuit (a variant of a circuit described by G. T. Evans in 1931).

The importance of applying the time-base-producing voltages symmetrically to the cathode ray tube is described in a chapter on push-pull deflexion, and the book ends with a description of methods of synchronizing or locking time bases to the frequency of occurrence of the phenomena under observation and with a note on the use of time base circuits for frequency division—a by-product of their usual application.

Some useful appendixes are added, dealing (among other things) with practical notes on the use of a cathode ray tube, linearity of exponential variations, the author's work in clearing up certain anomalies in the operation of gas-discharge valves, 'differentiating' circuits, and square wave generation (including the use of an artificial line for producing brief pulses).

A full table of contents, the clearness of which is enhanced by the use of four different type faces, a short bibliography and an index are included. The circuit diagrams which accompany the descriptions are numerous and clear.

The reviewer, while realizing that an author in war-time is subject to limitations of paper supply, thinks that the value of the book might be enhanced by certain additions. First: the author's standing in the 'time base' world fits him well for producing an authoritative glossary, which would include words such as scan, trace, firing, locking, square pulse, etc. Secondly: in his outline of the action of the multivibrator, the author adheres to the usual description, in which the back-coupling between the two valves produces a 'cumulative' effect which leads to instability. This simple description would lead to the idea that back-coupling *per se* leads to instability, whereas a gain 'round the circuit' greater than unity is a necessary condition. A more satisfying explanation is that the circuit (at first stable) is caused to arrive at such a condition that the gain is greater than unity, and instability results. A more comprehensive account, in terms of positive feed-back, is given in the chapter on trigger circuits. Thirdly: the author illustrates some descriptions with "Cyclograms" which show the path of the spot resulting from the simultaneous application of two voltages to the two deflecting systems. The time-variation can be inferred qualitatively by studying the relative thickening of the slowly moving traces, but the reviewer suggests that this information could, with advantage, be introduced quantitatively by modulating the beam by means of a square wave of known frequency.

L. BAINBRIDGE-BELL.

PLANT GEOGRAPHY OF THE MEDITERRANEAN REGION

Das Pflanzenkleid der Mittelmeerländer

Von Prof. Dr. M. Rikli. Lief. 1. Pp. 128+17 plates. 7.50 francs. Lief. 2. Pp. 129–240+17 plates. (Bern: Hans Huber, 1942.) 9 francs.

IN view of the importance of the Mediterranean region as the centre of origin of a great number of cultivated plants (Vavilov, *Trudy prikl. Bot. Leningrad*, 16, No. 2, 242; 1926) and of its interest to botanists and agriculturists in South Africa, parts of Australia, California and other localities where somewhat similar climatic conditions prevail, a detailed, documented account of Mediterranean plant geography such as that now being published by Prof. M. Rikli, of Zurich, himself a specialist in the subject, is much to be welcomed.

The work is appearing in serial parts containing approximately 120 pages. Two parts have been received in Great Britain. Although unfortunately no prospectus showing the ultimate extent of the book is to hand, a study of the existing fascicles sufficiently indicates its indispensable nature for the library of the botanist and the ecologist.

The matter treated in the first two parts comprises a definition of the Mediterranean region and its limits, with some reference to transitional zones; its climatic conditions; the life-forms of the Mediterranean flora and their phenology; and the beginnings of a classified account of the flora itself. One chapter is devoted entirely to a study of the olive tree, described as not only the most valuable tree of the region economically, but also the principal indicator of typical Mediterranean conditions, for where the olive tree ceases to appear, there is the boundary of the true Mediterranean flora. The seventh chapter, of which only a part (pp. 168–240) is included in the issues under notice, deals with the natural land of the region, treating first six groups of formations found in land capable of cultivation but not yet under culture. These groups are the forest, large and small shrub and rock gorge formations, and the less important marsh and strand formations.

In defining the Mediterranean region, three main divisions are recognized: (1) North Africa, comprising the Atlas countries (Morocco, Algeria, Tunisia) and the Barka countries (Tripolitania, Cyrenaica, Marmarika and Egypt); (2) southern Europe; and (3) near Asia. The last-named section is again divided into Orient I (Asia Minor, Cyprus, Syria, Palestine, Sinai Peninsula) and Orient II (the Caucasus countries; Ciscaucasia and Transcaucasia, part of Armenia, the southern shore of the Caspian). Orient III (Arabia, Mesopotamia, Iran, Irak, etc.) lies outside the region under consideration. An imaginary line dividing east from west runs from Trieste down through the Adriatic and Mediterranean east of Malta and crosses the African coast at the Tunisian-Tripolitanian frontier: it is noted, however, that this division is of an arbitrary nature, while on the north and south the region is fairly sharply defined by natural frontiers, namely, mountain ranges and deserts. The eastern limits of the region are the most debatable; but, although the Caucasus lands and the northern shores of the Black Sea no longer exhibit much of the typical Mediterranean flora, it is considered that they should be included in the region, as the Black Sea forms actually a part of the Mediterranean Sea, while the Caspian Sea was in geologically recent times in connexion with the Black Sea and thereby with the Mediterranean also. At the same time, the relativity of any plant geographical limits is stressed, and attention is directed to the marked contrast of the eastern part of the region, with its more continental climate and rainfall lower than in other parts of the Mediterranean, to the extreme west, where the climate is maritime and characterized by humidity and very abundant rainfall.

Of great importance for the especial character of the flora is the annual rainfall and its seasonal distribution. On the whole, the amount of the annual rainfall diminishes steadily from north to south, and, for the same latitude, from west to east. The actual quantities are not so low as the character of the vegetation might suggest—the mean figure given is indeed 9·3 per cent higher than that for Germany—but the greater warmth and drier air of the Mediterranean region, together with the drought-hardened soils, greatly increase the proportion of evaporation and run-off and reduce that of the moisture available to the plants. Seasonal distribution, however, is the weightiest factor governing the preponderantly xerophilous nature of the Mediterranean flora, for during the summer there is little or no rainfall, so that this season constitutes for the plants a season of rest. Atmospheric humidity, like the amount of rainfall, also diminishes from north to south and from west to east; and especially in summer, at the time of the greatest evaporation, the air is extraordinarily dry. Rainfall is generally of a torrential nature and of short duration. The temperature of the Mediterranean region is distinguished by a remarkable degree of uniformity, by high winter temperatures and generally very moderate minima, the average minima ranging from + 7·3° C. at Alexandria to −7·2° C. at Montpellier. Winds, general and local, the light climate—described as a "photochemical climate" akin to the intensity recorded for alpine heights—and the microclimate have also their part in conditioning the special nature of the Mediterranean flora. These life conditions are fully dealt with in Chapter 4.

While the great majority of the Mediterranean plant types, differing so greatly in habit, can be described as xerophytes, the following fifteen groups are distinguished and described: therophytes, geophytes, sclerophyllous plants, compass plants, trichophytes, secretory plants, armoured plants, microphyllous plants, virgate plants (Genista spp., *Spartium junceum*, etc.), thorn bush (thorns constituting an adaptation to drought and great intensity of light rather than a protection from animals), chamæphytes and hemicryptophytes, cushion plants, xerophytic Gramineæ, succulents, osmophytes.

The portion of the seventh chapter now at hand contains the section on the natural forests of the Mediterranean region—mainly oak, notoriously sparse and composing only 10–30 per cent of the total area—and a part of the section on the woods and large bush formations. Of particular interest, perhaps, is the account (pp. 221–236) of the widespread Mediterranean evergreen formation, the maquis. There are discussed its origin, its botanical composition, the conditions governing its existence and the modifications and displacements brought about through human activity and especially through large-scale burning for pasture. From personal observations in Corsica, it is estimated that the greater part of the evergreen bush of that island is burnt on an average once every six to ten years, "an expression of the age-long strife between the pastoral population, which desires to enlarge its grazing areas, and the forester".

The section on the pseudo-maquis, a more winter-hardy xerophytic evergreen bush formation occupying montane and submontane regions, is as yet incomplete.

References to the literature are placed at the end of chapters, and the work is copiously illustrated by maps and photographs. G. M. ROSEVEARE.

ROTATION AND THE PLOUGH

The Way of the Land

By Sir George Stapledon. Pp. 276. (London: Faber and Faber, Ltd., 1943.) 12*s*. 6*d*. net.

SIR GEORGE STAPLEDON is perhaps the greatest living example of a type of scientific mind which with increasing academic specialization and on account of the change in the nature of scientific inquiry towards the quantitative rather than the qualitative is less common than it was. He might be compared with the Darwins, John Bennet Lawes, and K. Timiriazev [see p. 138 of this issue] in being well known beyond the walls of universities and in having found his best inspiration outside the laboratory and with a social rather than a theoretical leaning. His bent may be called the generalizing descriptive, distinct from the taxonomic and the quantitative; it is clear from this book that he prefers the energetic to the inductive, and H. Bergson to R. A. Fisher. His greatest admiration for a man of science is bestowed on G. Turesson, the Swedish student of plant ecotypes.

Sir George is an appreciated popularizer of an idea, or rather a close-linked series of ideas, arising out of the study of the natural history of plants and intended to raise the status of his country's agriculture. These ideas are so well known that it is almost superfluous to mention them here. The book will be useful to the agriculturist who is unaware of Sir George's thesis—if there is any such person; it will be more useful still to the person who thinks he knows about the ploughing-up and rotation of grassland, and wishes to refine his knowledge.

The book consists of twenty-two essays and addresses dating from 1912 to 1942. Most of them have not been published in full before. The presidential address to the Agricultural Section of the British Association is included here, and deserves re-reading because it brings to light the curious neglect of the study of rotation. It suggests other instances of neglect of scientific consideration of problems of actual farming, such as give openings to critics of the organization of agricultural science. Together, the essays form what the publisher describes as the autobiography of a point of view. It is the point of view of an explorer eager to tell of what he has seen, and of what can be done, in a new land; but his *terra incognita* lies at home. He has discovered the grasslands of Britain, some of them high up, where few besides the shepherd and the farmer ever tread; others, low down, and traversed by the railways and hunting packs of central and southern England. He has discovered the potentialities of the often-overrated grazing land; how there is scarcely any that cannot be improved and made farmable by being ploughed up and wisely managed. For once, the better will be the friend, and not the enemy, of the good. Characteristic is the observation that much land that was permanently hayed has had its fertility transferred via the stables of the big towns to the market gardens, which are sinks of fertility.

The ideas of Stapledon actually affected only a small proportion of the vast campus over which he would like to operate: a few hundred acres at most owe their improvement directly to him. But the seed was only dormant. There cannot be much doubt that the way of the land in current agricultural policy is in part its fruit: to this Churchill among agronomists his hour came. The present value of this book is difficult to assess. To some, the book may seem redundant, but perhaps there is an implied tribute in that. The value of this work will almost certainly be great to the agricultural historian of fifty years hence, who will see clearly developments hidden from us either because they are contemporary or because they have not yet come fully to fruition.

HUGH NICOL.

Fluid Mechanics and Statistical Methods in Engineering

By Hugh L. Dryden, Theodore von Kármán, Anton A. Kalinske, Thomas K. Sherwood, Samuel S. Wilks, Walter A. Shewhart, Leslie E. Simon, Roscoe Pound. (University of Pennsylvania: Bicentennial Conference.) Pp. v+146. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1941.) 10*s*. 6*d*. net.

THE book is divided into two sections, each consisting of separate papers of a mainly expository character. The best idea of such heterogeneous material will be conveyed by enumeration. The first section, "Fluid Mechanics", contains four papers. "The Role of Transition from Laminar to Turbulent Flow in Fluid Mechanics", by H. L. Dryden, gives an introductory survey of the various aspects of the problem of transition, with diagrams. "Problems of Flow in Compressible Fluids", by T. von Kármán, gives a short review of a few problems connected with high-speed flow and high-speed motion of solids in fluid media with particular reference to aeronautics and exterior ballistics. "Investigations of Liquid Turbulence and Suspended Material Transportation", by A. A. Kalinske, gives an account of transportation of suspended matter in an open channel. "Mass Transfer and Friction in Turbulent Flow", by T. K. Sherwood, gives a brief discussion of various theories proposed in this connexion.

The second section, "Statistical Methods in Engineering", also contains four papers. "Contribution of Mathematical Statistics to Scientific Methodology", by S. S. Wilks, gives an account of the principles and scientific significance of the methodology for making predictions from observations, together with the appropriate measurements of confidence. "Contribution of Statistics to the Science of Engineering", by W. A. Shewhart, gives an outline of the theory of repetitive operations on order to provide the engineer with a method of regulating such operations to the best advantage. "Contribution of Statistics to the Development and Use of Purchasing Specifications and Standards of Quality", by L. E. Simon, outlines the genesis of a statistically sound acceptance specification. "The Relation of Statistical Quality Standards to Law and Legislation", by R. Pound, inquires whether statistical methods cannot be used to point the way in certain aspects of legislation.

In so far as the articles are expository they may appeal to the general scientific reader interested in such matters; indeed it is difficult to see for whom else the collection can be intended.

Apparitions

Being the Seventh Frederic W. H. Myers Memorial Lecture, 1942. By G. N. M. Tyrrell. Pp. viii+123. (London: Society for Psychical Research, 1943.) 3*s*. 6*d*.

IT might be thought that Mr. Tyrrell, in choosing the subject of apparitions for the seventh Frederic W. H. Myers Memorial Lecture, was returning to that kind of anecdotal psychical research which is gradually giving way to a more quantitative and philosophical approach. Such, however, is not the case, for in this lecture Mr. Tyrrell is approaching the subject of apparitions from the only angle from which such phenomena can be properly approached, namely, that which supposes such appearances to be in general hallucinations of a peculiarly interesting and important kind. Mr. Tyrrell supposes that apparitions are caused by the existence of what he calls "idea patterns", by which he means images which are the direct expressions of the agent's ideas and which are externalized as full-blown hallucinations. What is seen is, to use Mr. Tyrrell's phrase, merely "a psychological marionette", the outward expression of a drama which has been thrown into sensory form, and thus a close and detailed study of its production might be expected to throw considerable light on the various strata making up the human personality. It is true that the facts of collective hallucination and similar experiences, which are apparently shared by both children and animals, are not altogether easy to fit comfortably into the framework Mr. Tyrrell has constructed for them; but generally speaking it would be a mistake to lay too much emphasis on incongruities and difficulties which may eventually be found to be superficial rather than fundamental. What Mr. Tyrrell has done has been to direct attention to the need of examining apparitions from the psychological and philosophical points of view; and such an attempt can only be made by those who have rid themselves of naïve assumptions bred from prejudice and lack of acquaintance with the facts. Such an approach is to be welcomed and will, it is hoped, be extended to other branches of the studies comprised under the comprehensive title of psychical research.

An Encyclopædic Dictionary of Science and War

By Surgeon Rear-Admiral C. M. Beadnell. Pp. xviii+293. (London: Watts and Co., Ltd., 1943.) 25*s*. net.

IT is in the nature of things that one is more intensely critical of dictionaries than almost any other documentary material, so let it be said at once that the present volume is a remarkable achievement for a single author. He is well known as a lifelong student of ballistics, and, carefully avoiding the ground recently covered by other technical dictionaries and encyclopedias, has contrived to concentrate on ballistics and such sections of chemistry as explosives, war gases, and the elements, as have primary functions in war-time. Where desirable, extensive tables give the data in easily accessible form, with one dire exception: if one requires any of the mass of information which is given about an element, one is retarded by the time required to disentangle each item, since for each element the items run on. There are inevitably some obvious misprints in these masses of data. Much space is saved for useful information by a considerable series of contractions, which are listed separately.

While one might insist that the volume be titled "Science in War" instead of "Science and War", one can also blame the author in not being scientific in his diverse use of dimensions. Any magnitude is inevitably accompanied by its translation from, say, inches to centimetres, miles, etc., seconds into hours or years. The author might consider being more scientific in a new edition by adopting throughout the metric system in multiples of 1,000. The inevitable simplification of units in the future would be accelerated if authors of such standardizing books as the present show a lead and indicate the public usefulness of the metric system.

L. E. C. HUGHES.

EDUCATIONAL RECONSTRUCTION

THE long-awaited White Paper* setting forth in full the Government's policy and intentions in the matter of educational reform is now before the public, and will no doubt be discussed from every point of view. For the moment we confine ourselves to a summary of its principal proposals, reserving further comment for a later date. The cautious mode of procedure adopted by Mr. Butler commands general approval. The teachers, the administrators, the churches, the parents, and the existing local authorities may now know just where the Government stands, and are free to criticize before an Education Bill is introduced in Parliament. No one who recalls the stormy scenes of 1870 and 1902, and the fate of some of the best proposals of 1918, can wonder at Mr. Butler's studied patience and wariness. As in 1918, the fact that the coming Bill will be introduced on behalf of an all-party or non-party Government will facilitate its passage through Parliament, but it is to be hoped that it will do so with ultimately better results.

The Paper envisages national education in three stages—primary education, secondary education, and further education. The traditional term 'elementary', which has long been a rather absurd anachronism, will now disappear from the official vocabulary. No longer will it be implied that teaching the 'elements' of the three R's is almost the *raison d'être* of the people's schools, and no longer will the parent's duty be confined to causing his child to be efficiently instructed in the three R's. His duty, as laid down in this Paper, will be "to cause his child to receive efficient full-time education suitable to the child's age and aptitudes" (par. 24).

Primary education is defined as covering the period up to eleven or twelve. The age for compulsory attendance at school, namely, five, will remain as now. Primary education is to include the nursery school, for children from two to five, the infants' school, for children between five and seven or eight, and the junior school, for children between seven or eight and eleven or twelve. Here we seem to have a convenient fixing of terminology which was necessarily left rather fluid in the Hadow Report on the primary school. There is now to be a comprehensive stage of primary education, of which the last part is the junior stage. As to nursery schools, the weak word "may" is to be replaced by the mighty word "shall". Otherwise expressed, "it is proposed to substitute for the present power of local education authorities a duty to provide, or aid the supply of, such nursery schools as in the opinion of the Board may be necessary". Good reasons are given for preferring self-contained nursery schools to nursery classes attached to infants' schools. Though no special prominence is given to the subject, the proposed provision for nursery schools is, for its social consequences, probably the most far-reaching thing in the whole document. Good reasons are again given for separate infants' and junior schools, wherever the numbers justify the arrangement. The psychological differences between the two stages are in general a part of "what every woman knows" and many men also. The very large classes in many infant and junior schools are condemned unsparingly as affording "not education but mass production".

One of the most striking passages in the White Paper, also far-reaching in its educational consequences, is the condemnation (par. 17) of the present arrangements for transition from the junior schools to the post-primary schools. "There is nothing to be said in favour of a system which subjects children at the age of eleven to the strain of a competitive examination on which not only their future schooling but their future careers may depend. Apart from the effect on the children, there is the effect on the curriculum of the schools themselves. Instead of the junior schools performing their proper and highly important function of fostering the potentialities of children at an age when their minds are nimble and receptive, their curiosity strong, their imagination fertile and their spirits high, the curriculum is too often cramped and distorted by over-emphasis on examination subjects and on ways and means of defeating the examiners. The blame for this rests not with the teachers but with the system." So it is proposed to make a clean sweep of this unhealthy form of competition, a competition which is pernicious at any stage.

Coming now to secondary education, we observe that there are to be three types of secondary schools, to be known as grammar, modern and technical schools. The grammar school will be of the type represented by the present secondary schools, and the modern schools will be of the type represented by the existing central and senior schools. It is fully recognized that there are, in areas where re-organization has taken place, enormous differences between the two as to premises, equipment, staffing and what are called amenities but could often be more correctly described as decencies. Meantime the word 'secondary' is to be hopefully applied to both types, as well as to the technical schools, which have achieved so much success since they were started in 1905. The intention to raise the leaving age to fifteen without exceptions as soon as possible after the War, and to sixteen at a later date, will of course have an important effect on secondary schools of all types. A child who is found, say, at the age of thirteen, to have been wrongly placed at the age of eleven may be transferred to a school more suitable for his bent and talents.

From the fact that religious education and the position of the voluntary schools occupy far more space than any other topic, amounting to nearly a quarter of the whole Paper, it may be inferred that the old difficulties have been fairly faced. One thing is clear. There is a very general wish, not confined to representatives of the churches, that religious education should be given a more defined place in the life and work of the schools. The practice now prevailing in most primary and secondary schools of beginning the day with a corporate act of worship will now receive statutory sanction and be universal, but with due regard to the rights of conscience. In what we now know as provided schools the religious instruction will usually be in accordance with an agreed syllabus. No unwilling teacher will be compelled to give such instruction, and no teacher will be penalized for not giving it. Also, it is at last recognized that there is no valid reason why different principles should be applied to inspectors and teachers. The inspection will be limited to agreed syllabus instruction. As we have intimated, much space is devoted to the embarrassing dual system, including ts history, and the reasons why the simple solution reached in Scotland is inapplicable south of the Tweed. A plan is described by which the degree of public control will be approximately proportioned to the amount of financial support provided from public funds.

---

* "Educational Reconstruction." Cmd. 6458. (London: H.M. Stationery Office, 1943.) 6*d.* net.

The principles of the Act of 1918 relating to day continuation schools are to be adopted to meet the requirements of the post-war world, but the term "day continuation school" is to be abandoned, and the institutions required for the purpose will be referred to generally as 'young people's colleges'. "It is important," says the Paper, "to make clear that what is in view is no 'going back to school', a mere extension on a part-time basis of previous full-time schooling, but the entry on a new phase of life and development." Certain basic elements will be included in the training, and when these have been met the remaining hours may be devoted to a variety of subjects according to the needs and capacities of each individual.

The field covered by the term "further education" is obviously a wide one. The provision of further education is at present a power and not a duty of local authorities, and despite what many authorities have done, technical education has not made the advance which the needs of a highly industrialized community demand. To some extent the industries themselves are alive to the need of ordered systems of training, and by consultation with the Board of Education and the Ministry of Labour it is hoped to build up in each major industry a system which will be accepted and applied not by individual firms here and there, but on a national basis throughout the industry.

The White Paper emphasizes that without provision for adult education the national system must be incomplete. After all has been said about other forms of education, it is "within the wider sphere of adult education that an ultimate training in democratic citizenship must be sought". While the more serious and solid studies that have formed the backbone of adult education at its best must be maintained, there will be room for new methods and new approaches to meet new demands. Upon this question the education services that have operated in the Forces have thrown much light.

Mention is made in the Paper of the Youth Service brought into being to extend the recreational training of young people by assisting the voluntary organizations. In spite of the restrictions imposed by war conditions on the supply of leaders, premises and equipment, the service has shown a remarkable expansion. "There is now a far higher proportion than at any previous time of young people associated with healthy leisure-time training and recreation without compulsion or regimentation of any sort." The section on health service, we may add, extends existing facilities for securing the physical well-being of children and young persons.

On the subject of access to the universities, it is noted that the path of the poor scholar has been made broader and less difficult during the last twenty years, and that the expenditure by the Board through the system of State scholarships and by the local education authorities through their major awards has been a profitable investment, judged by the successes achieved by the beneficiaries. None the less, the system is inadequate. Again the difference between giving a power and laying a duty upon a local authority obtrudes itself, leading to a wide disparity in the opportunities of poor students. Upon this question the Norwood Committee's advice is now available for the guidance of the Government. The Paper hints that this is not the only direction from which provision may be made for highly promising persons after the War.

At various points in the course of the Paper the reader is reminded that legislation can do little more than prepare the way for reform. "It will rest with the Board and the local authorities, and, not least, with the teachers working in the schools, to translate its aims into practice." All along the line, through primary and secondary and further education, it is obvious that more, a great many more, teachers will be needed. But, says the Paper, it is not merely a larger number of teachers that will be required, but a larger number of the right kind. "It would be deplorable if the necessary corps of teachers could be obtained only at the expense of lowering existing standards. It depends almost entirely upon the quality of those who staff the schools whether the reforms proposed will be merely administrative reforms or whether they will, in practice, work out as real educational reforms." These questions of the supply and training of teachers are being investigated by the McNair Committee, and the recommendations of that Committee are awaited. Meantime the Paper points out frankly what is "patently wrong" with the present system of recruiting and training teachers, and some of the reasons why an expert inquiry was long overdue. The field of recruitment is narrowly limited to those boys and girls who remain at grammar schools until 17 or 18, and the educational history of teachers is nearly all of one uniform pattern. As to the period immediately following the War, "there are many men and women now serving in the Forces or elsewhere whose experience and devotion would greatly enrich the education of children".

The Paper concludes with some plain speaking on the subject of "independent schools", that is, schools which stand apart from the State system. The expression includes all manner of establishments, from those which are excellent to those which, according to the report of a Departmental Committee in 1931–2, are so defective as to be harmful to the physical and mental welfare of the children, and those —a larger number—which are seriously deficient and inefficient. At present anybody, whatever his or her qualifications, can start an independent school in any building and, unless the use of the building constitutes a nuisance under the public health acts, its improvement or closure cannot be obtained. The Paper proposes that all independent schools must be open to inspection by the Board and registered on a list kept by them, and that schools found to be defective shall be suitably dealt with. It is characteristic of our national feeling in such matters that, in order to ensure that reasonable liberty shall remain for those schools outside the public system, the proprietor of a condemned school will have the right to appeal to an independent tribunal against the Board's decision.

Such are the main contents of a document, remarkable alike for its comprehensiveness and its lucidity, which will provide thoughtful citizens, both young and old, with food for thought during the next few months. No doubt much of further interest and value will accrue from the Parliamentary debates which will follow.

ADOLESCENCE AND SOME PROBLEMS OF YOUTH TRAINING*

By PROF. C. W. VALENTINE
University of Birmingham

IN a short article one can of course attempt no comprehensive survey of the psychology of adolescence. I propose merely (i) to supply further evidence on some points in view of the revived interest in the training and guidance of youth, (ii) to question one or two assumptions usually made, and (iii) to indicate certain basic problems.

As my first section below gives results gathered by means of questionnaires, a word may be said on the scientific value of such inquiries. Provided that these reports are anonymous, as in my own inquiry, I am sure that one can gain valuable information from them. In using questionnaires, however, one must beware of distributing them widely and then only dealing with the selected records of those who have taken the trouble to reply. Such are liable to be those who have something particularly interesting to report of their adolescence, or those who enjoy the opportunity of writing about themselves. The danger is avoided when one presents the questionnaire to a group of people and gets replies from every one, though of course we have to bear in mind the selected nature of the class itself, in this case university graduates. My own questionnaires were filled in by 220 graduate students during the years 1926, 1927, 1930 and 1942. Similar inquiries among students and wage-earners were made by Prof. Olive Wheeler[1]. In addition, I had some hundred or so confidential essays from students based largely on their own adolescent experiences, which were astonishingly frank. (I guaranteed that no one should read them except myself.)

The students (120 women and 100 men) were asked whether they had experienced during adolescence a marked intensification of various kinds of emotional experience or a decided change in certain attitudes, and to give the ages at which these changes began and ended. I give some of the most interesting results.[2] Marked increases or intensifications were reported as follows: as to religious experiences, women 74, men 78 per cent; interest in a member of the same sex (something approaching 'love'), women 72, men 50 per cent; aversion from opposite sex (at an earlier period usually) women 45, men 45 per cent; moods of intense dejection, women 76, men 61 per cent; contemplation of suicide, women 29, men 38 per cent.

There is general agreement that some of the main characteristics of adolescence, especially the instability of emotions and impulses, are closely connected with, if not entirely dependent upon, the maturing of sex. A point here which is apt to be overlooked is the wide range of ages at which sex maturity arrives. For example, among girls in the United States, one quarter begin menstruation before the age of 12½, one quarter do not begin until after 14½[3]. While there does not seem to be a complete correlation between puberty and the mental stages, the very close connexion is enough to caution us against treating a given set of children of twelve or fourteen or sixteen years of age as essentially at the same stage of development.

Further evidence in support of this is found in the great variations in the age at which various characteristics appear. Thus in women moods of intense dejection began so early as twelve, in others not unti nineteen or twenty years of age; a keen interest in the opposite sex began in some so early as eight, in others not until twenty; strong aversion from the opposite sex varies from eight to sixteen or never Among the men an expectation of future greatness appeared at varying ages from eight to eighteen, or never.

The confidential essays revealed that many adolescents imagine their strange moods and impulses to be unique, which creates a feeling of intense loneliness.

The main sources of mental trouble seemed to the youths to be intense self-consciousness (accentuated if there was excessive size or extreme awkwardness), distress at social evils which seemed insoluble (unless the individual could have a free hand to deal with them), unhappy relations with parents, struggles with doubt about religion, sometimes disgust or fear at the first experience of sex emotions, or, in the case of girls, of premature advances by boys or men. There were also comments which confirm the view that the adolescent's wish to be independent of his parents' support and to feel himself a 'man' and enjoy greater freedom is a main cause for wishing to become a wage-earner at fourteen or as soon as possible.

One thing is clearly demonstrated by some of the essays, namely, that some of the intense feelings of inferiority during adolescence were consistent with remarkable strength or ability clearly demonstrated a few years later, even in those very things in which weakness had been felt. Thus several students who experienced intense feelings of inferiority and lack of confidence did brilliantly at the university and took a prominent part in the university life.

Another fact which emerges clearly is that some of the girls who had most intense feelings of affection for older girls or mistresses—real 'crushes'—turned out to be among the finest in character and ability at university stage. Some of these girls had been caused great unrest—acting like fond doting lovers—kissing the book lent to them by a beloved mistress, walking up and down the road past the house where the loved one lived, and so on.

In another inquiry I made in which students who had been at co-educational schools were compared with those at boys' or girls' schools, such homosexual attractions were far less frequent in the co-educational schools, and students from these schools were almost unanimously in favour of them.

Should we Discuss Adolescence with Adolescents?

A practical problem arises as to how far we could help the adolescent by letting him know that the great variations of mood, of extreme elation and dejection, or the contemplating of suicide, are often passing phases of the adolescent life. Such talks have indeed been suggested by some important bodies dealing with the training of young people. It would seem helpful to inform an adolescent that he is likely to be subject to extreme moods and, in particular, that he is not alone in the unhappy inclinations to run away from home or even to commit suicide. My own reports show clearly that many adolescents feel a greater distress because they think their own inner struggles are unique. On the other hand, to speak to adolescents of the common intensification of religious interest, or of high ideals, as passing characteristics of this adolescent phase, or of the expectation of accomplishing great things in life as a common illusion, would seem clearly undesirable.

---

* Based on a paper read before the annual general meeting of the British Psychological Society at Oxford during April 8-12.

One matter at least could be spoken about, namely, the plain facts of sex development. It is clear that even in these days, in some cases, young people are allowed to experience the first signs of physical maturity without having been warned beforehand. In my own work of giving psychological analysis and treatment, I have known several cases in which great early distress due to ignorance about sex development set up neurotic conditions lasting for a considerable time, indeed until relief followed the discovery of their origin.

Delinquency during Adolescence

It is too commonly assumed that the main cause of juvenile delinquency is the removal of the child from school at too tender an age into the socially dangerous life of the young worker. But if we take into consideration the relative population for each age, it appears that thirteen is the age at which the percentage of juvenile delinquents is greatest[4]. When boys leave school and become wage-earners, delinquency actually decreases.

Reference to the figures will also show the surprisingly high numbers for delinquency among boys at the ages of twelve, eleven and even ten, in spite of the reluctance to bring delinquencies of younger children to official notice. Hence we cannot assume that the major cause of juvenile delinquency, among boys at least, is the removal from school and the mixing with older men, or the greater freedom due to employment, though for many, no doubt, it is a precipitating factor.

Among girls the frequency of (reported) delinquencies is, of course, very much lower than among boys (about one tenth) and the peak age is appreciably later in adolescence; this is no doubt due largely to the fact that such a considerable number of girl delinquencies are connected with sex.

In several inquiries it has been shown that juvenile delinquents are less often members of youth clubs than are their opposites in the control groups. Mr. W. L. Chinn found, among 1,000 juvenile delinquents in Birmingham, that only 31 per cent belonged to "recognized social organizations", while among the controls 61 per cent belonged to them[5]. (Chinn included children from the age of ten up to fifteen. The figures for children between fourteen and fifteen were: delinquents, 17 per cent; non-delinquents, 53 per cent.)

One important question, however, has to be borne in mind in considering such results. We do not know how far such differences are due to the fact that it is the 'good', socially well-adjusted boys who choose to become members of clubs, while those more inclined to delinquency are indifferent to such clubs; or, how far the difference is due to the good influence of the clubs upon the boys who do join them. The importance of selection seems undoubted. An examination of the results found by Carr-Saunders and his colleagues in the recent inquiry[6] confirms this view. They first of all eliminated from their consideration the 'abnormal' homes ('broken' homes or homes where there was bad discipline, or undue friction between the parents, or where one of the parents was unemployed or in bad health, or failed to reveal regular and exemplary habits). Taking only the 'normal' homes, they found the following figures:

REGULAR CLUB MEMBERSHIP

	London	
Delinquents	(273 in number)	29 per cent
Controls	(550 in number)	35 per cent
	Provincial cities	
Delinquents	(264 in number)	28 per cent
Controls	(539 in number)	30 per cent

In other words, where the homes were fairly satisfactory, regular club membership made very little difference as to delinquency.

This leads us, however, to ask another question. What would the figures be if these investigators had found the figures for *abnormal* homes? It is precisely among children from homes with bad influence that we should expect clubs to be most valuable. It would also be of great interest to find how the proportion of adolescents joining some club was affected by their coming from 'normal' or 'abnormal' homes. The same principle of selection applies to the figures for attendance at a church, when there was only a difference of 10 per cent between delinquents and controls. The figures for *attendance at evening schools* show still greater difference—only 7 per cent for the delinquents, nearly 33 per cent for the controls. Again we cannot of course assume that the evening schools had much direct influence on the tendency to delinquency or that compulsory attendance at evening schools would reduce delinquency. The main reason for the difference is again probably that the more serious, ambitious, or obedient pupils would attend evening schools, though no doubt occupation on some evenings would lessen the temptation to commit petty offences.

As to *home discipline*, there was a decided difference between the delinquents and the controls. In less than 60 per cent of the delinquents' homes was the disciplinary attitude satisfactory, whereas the figure for the controls was nearly 90 per cent. We may recall that Burt found that bad discipline in the home gave the highest correlation with delinquency, of all the factors he examined[7]. This confirms the view that the problem of delinquency and the training of youth cannot be solved by treating the youth himself in schools or clubs. It must also be tackled in the home itself, and some attempt made to educate parents in at least elementary principles of discipline. In interviewing (with school attendance officers) the parents of children who had been persistent absentees from school, I have been appalled at the stupidity of the attempts at discipline—or lack of them—to which parents confessed. I have no exact figures, but my general impression is that considerably more than half the difficulties were chiefly due to this: and if we include frequent illnesses in which there was also subsequent over-indulgence and lax discipline, nearly all cases would be covered.

One fact that is often overlooked is that many youths seem to survive the worst possible environment, while others succumb even in the most favourable environments; for example, more than 40 per cent of the delinquents come from normal homes where the atmosphere and discipline seemed satisfactory; while nearly 30 per cent of the non-delinquents come from homes without such normal atmosphere. These facts lead the authors of "Young Offenders" to a conclusion similar to that I drew from investigations as to younger children[8], namely, that (i) there are some children who will develop sound characters in almost any type of environment; (ii) there are some who will go astray even in the best types so far as we can discover it; and (iii) there is a large intermediate section whose development will be profoundly affected by their environment.

The Youth Movement and Club Membership

The recent registration of youths, and the recommendations given to them to join some youth organization, should provide valuable material for the study of youth training, particularly if careful follow-up studies are made as to what happens to those who are not already members of some 'approved' organization. In Birmingham a report made to the Education Committee in September 1942 revealed that some 47 per cent of the boys aged sixteen and seventeen were not undertaking any 'approved activity' (which included junior service organizations) and were not receiving any systematic education. As to girls, it was found that as many as 73 per cent were not engaged in any approved activity. It should be noticed that the proportion of girls without 'approved activities' was actually greater at seventeen years than at sixteen, the figures for girls of the latter being 69 per cent and those of the former 77 per cent.

All young persons who were not attached to some organization were urged to join one and given an introduction to one of their own choosing. Only 18 per cent of the boys and 29 per cent of the girls were unwilling or unable to achieve introductions to such organizations. The larger organizations were afterwards asked to give their reports of the result of these introductions.

Reports as to boys were received from the Cadets, A.T.C., Navy League, Boys' Brigades, Boy Scouts, and Boys' and Girls' Union. None of these obtained more than a few new members, and many of these disappeared in a few weeks. The same was found for girls in the G.T.C., J.A.C. and Boys' and Girls' Union, but the Y.W.C.A. retained a considerable number.

Reports suggested that the long hours many juveniles were working, the need for help from the girls in the homes, especially where the mothers were working in factories, and the objection of parents to young people being out after 'blackout', all militate against the joining of organizations[9].

Even if the statistical evidence is not conclusive as to the value of club membership, few would doubt, on the mere basis of the general psychology of adolescence, that it is desirable to expand the provision for healthful and cultural leisure pursuits and also of opportunities for useful service.

The question of compulsory membership of youth organizations is a difficult one. It is agreed, of course, that education must be compulsory even if the youth himself would at the time prefer to do without it. If we accept this principle, then, so far as the Youth Movement includes 'educational' items, compulsion might seem to be justified by the same principle, at least up to corresponding ages, for those not continuing in full-time or part-time education. Another complication is the enormous variety of clubs and organizations, some of which can provide educational facilities, while others can only cater for recreation.

The whole matter is complicated by the question of continuation school education. If this were s organized as to provide essential education, yout organizations need only cater for additional interest and supplementary courses and recreations.

As to recreative pursuits, many hold that the whol atmosphere of the Youth Clubs would be spoilt i any element of compulsion were introduced, an indeed even compulsory educational courses migh tend to create the unpopular atmosphere of a 'school'. No doubt the ideal is that the leisure activities should be so attractive as to need no further stimulus. Th highly successful Sherbourne Youth Club in Birmingham, though catering for the roughest types of youths, has been able to impose compulsory attendance at some educational activity through the attractive power of its recreations, and still expand beyond capacity.

On the other hand, young people need at least some *information* as to what facilities are open to them. The Birmingham inquiry showed that often a youth ceased to attend some club after only one or two visits. But how many adults enjoy a first night alone in a holiday hotel, or what man is at ease the first day or two in a new club?

I suggest that some compulsion—or at least some compulsory choice of several alternatives—may be desirable, but only *for a time*, in order to give the youth the opportunity at least of judging whether this particular activity appeals to him, it being made clear to him that this is the only reason for compulsory attendance.

A further question arises as to whether there should be some compulsory form of service for the community. It is not the concern of a psychologist to discuss the rights and wrongs of State control, State propaganda, or the question as to how far the State should demand service of its young people. I merely wish to suggest here that we cannot assume, as is often done in educational discussions, that, because some service is made compulsory during adolescence, the youth will therefore become accustomed to this, and so become less selfish and give service voluntarily later on. This, I suggest, would only happen if in doing such compulsory service the youth discovered a new satisfaction and interest which he realized he would have missed otherwise. It is possible, indeed, that the compulsion to carry out 'good deeds' may have the opposite to the desired effects.

We should therefore look askance at such vague phrases as 'training youths to be co-operative' or 'unselfish', which are so often used in discussions on education, and we should demand much more specific statements as to *how* such 'training' is to be made permanently effective.

Finally, so far as service is appealed for, among our young people, it should surely be based on the ground that their help is needed and useful, and not that it is good for them. Indeed, it is only service given on such a basis that is in fact likely to be 'good for their soul', for it is that which will appeal to them most.

TEN YEARS OF GROWING EXCISED TOMATO ROOTS

By DR. PHILIP R. WHITE

Rockefeller Institute for Medical Research, Princeton, New Jersey

MARCH 1, 1943, marked the decennial anniversary of the starting of the first uninterrupted cultures of excised plant organs[28]. The root tip from which was derived the standard clone now used in all experimental studies on excised roots carried out in this laboratory was severed from its seedling parent on March 1, 1933. This root is still growing. From it have been made some 80,000 experimental cultures. In addition to these cultures for which increment data are available, large stocks have been maintained on which detailed records were not kept. The total measured increments represent many kilometres of growth; the theoretical increments[28] amount to staggering figures (*ca.* 10^{2800} kilometres). It seems appropriate at this time to review briefly the history and behaviour of this clone.

Aseptic seeds of Bonny Best tomato were sown on sterile filter paper late in February 1933. When, on March 1, the seedling roots had attained a length of a centimetre or more, twenty-five of them were excised and each one placed in a separate flask. The nutrient[24] was, as was soon discovered, not a very satisfactory one. Only one of the 25 roots grew. This was transferred on March 13 to fresh nutrient of a somewhat different and more satisfactory formula[28]. From this root, during an initial period of ten passages averaging 13 days per passage (127 days), a clone of 100 cultures was built up. This number was maintained through 42 subsequent passages of 7 days duration each (294 days), during which time each culture was measured daily. At the end of the fifty-second passage (421 days) the number of cultures in the measured stock was reduced to 25 and measurements were recorded thereafter only at the beginning and end of each weekly passage. Measurements of initial length, final length, number of branches, and length of longest branch together with notes on general behaviour were recorded for each culture.

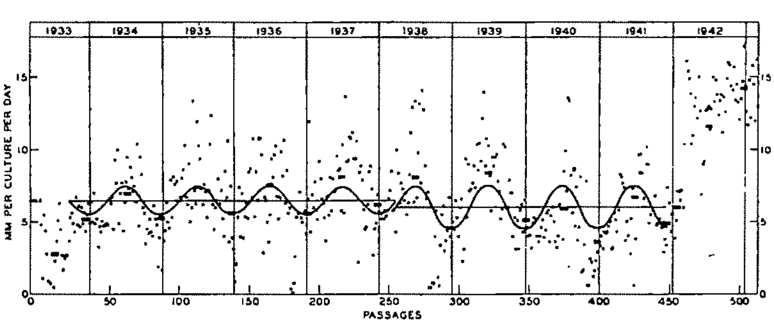

Chart showing the week-by-week increment rates of a single clone of growing excised tomato root tips over a period of ten years (523 passages). Each dot represents the average increment of 25 cultures during a single week (see text for exceptions in the first 52 passages). The average for each 26-week inter-equinoctial period is shown by a thick horizontal dash. The sine curves are drawn with nodes at the equinoctial points, the maxima and minima being drawn to correspond with the mean summer-winter fluctuations for the particular long-term periods represented by each distinct base line.

Transplants were made wherever possible by severing a piece about 15 mm. long from the apex of the culture[94]. Where, as occasionally happened, a culture became contaminated or the apex ceased to grow normally, this procedure, of course, became impossible. Such cultures were replaced where feasible by using the tip of a branch root which had already acquired its own dominance equal to that of the apex and was thus capable of equally rapid initial growth. This state is usually attained in tomato roots when the branch has reached a length of about 20 mm.[94]. When such branches were not available, fragments of the main root carrying one or more growing points which had not yet acquired this individual dominance were used as explants. Records were kept in such a way as to distinguish between these three categories: primary apices, secondary but dominant apices, and secondaries lacking established dominance, since cultures of the third category, in particular, usually showed a considerable lag in increment until some one branch acquired its own dominance.

A number of points of interest appear in the growth record for the ten years (512 passages). It has already been noted[48] that the average growth-rates, in spite of their wide and apparently random week-to-week variation, nevertheless approximate a sine curve when grouped in 26-week blocks beginning at the vernal and autumnal equinoxes. The average increment-rate for the entire ten years was 6·73 ± 0·15 mm./cult./day. If we ignore the initial 20 passages which preceded the establishment of a standard procedure (average increment 3·05 ± 0·42 mm.) and begin with the autumnal equinox of 1933 (passage 21), there was no significant change in *average* increment-rate until the vernal equinox of 1938 (passage 254), that is, during the first 4½ years. Throughout this time the nutrient consisted of a modified Uspenski salt solution, sucrose, and yeast extract, and the original standard procedure was maintained. The average growth-rate for this period was 6·47 ± 0·15 mm./cult./day. The average summer rate was 7·47 ± 0·27 mm., while the winter average was 5·60 ± 0·15 mm./cult./day. The difference between these, 2·22 ± 0·24, is 33 per cent of the average value—hence highly significant.

The interval between the vernal equinox of 1938 and a time shortly after the autumnal equinox of 1941 (passage 447) represents a second important culture period (3½ years). During this period a number of changes in procedure were tested. Chief among these was the substitution of glycine[77], thiamin[40,43,52], and certain accessory salts[64] for the yeast extract employed throughout the earlier period. These irregularities and changes in procedure resulted in a slight decrease in mean increment-rate and a concomitant increase in range of variability to 6·06 ± 0·22 mm./cult./day. The decrease is statistically of doubtful significance, the difference being − 0·47 ± 0·24 mm. With passage 448 a new and improved inorganic nutrient was introduced[92]. This resulted in an apparent improvement in growth (4·9 ± 0·3 to 6·1 ± 0·9 mm. in the consecutive 13-week periods representing equivalent segments of a single inter-equinoctial period), but the period tested was too short for the difference to be statistically significant (difference = + 1·29 ± 0·9 mm.). With the vernal equinox of 1942 a more important change was made. At this point pyridoxine and niacin were introduced[91] into the nutrient according to the recommendations of Robbins and Schmidt[74–76] and Bonner[78]. This resulted in a sharp increase for the following year to a level of 12·6 ± 0·8 mm. The increase here, over the previous mean rate, was + 6·1 ± 0·8, hence highly significant. This last nutrient has been used for too short a time (54 passages) to establish a new seasonal cycle. The results so far suggest, however, that the seasonal cycle may become much less pronounced in this nutrient. The impression given is that the great number of nutrient materials available and the more nearly optimal complex of environmental conditions provide a buffer against the injurious effects of certain variables, especially temperature fluctuations[49]. This is presumably comparable to the means by which field conditions permit plants to survive and prosper under a range of variables to which they would succumb in the laboratory.

The random week-to-week fluctuations observed throughout the ten years are, for the most part, not capable of interpretation. The causes of a few are, however, known. The sudden drop in the 179th to 181st passages is such a one. This almost resulted in loss of the entire clone, for in the 181st passage, out of the 25 cultures only a single one, No. 12, survived. The entire clone was recovered and re-established from this single root tip, and even in this case the primary tip and all six of the secondary tips were killed, the meristem being recovered from nine newly established tertiaries. The cause of this near-tragedy was traced to a split in the condenser tube of the still used in preparing distilled water, allowing tap water to pass into the supposedly pure water supply. This was not city water but came from deep wells. The toxic agent is not definitely known but was probably a trace of lubricating oil shown to be present in the laboratory water supply in considerable quantity. When this condition was corrected the cultures recovered rapidly, and by the 184th passage had been built up to full number (25) and a normal increment rate (5·3 mm. as against the idealized average for that time of year of *ca.* 6·6 mm.). The sudden drop in the 228th passage was correlated with and probably the result of a very sharp drop in room temperature[49], such as sometimes occurs in mid-September. The windows of the laboratory had been left open following a very hot day, and a sudden fall in outdoor temperature was paralleled by that indoors, resulting in thorough chilling and excessive condensation on the walls of the flasks. Recovery from this was as abrupt as its incidence. The low general level between passages 279 and 287 coincided with a period of illness during which the clone was maintained by a relatively inexperienced assistant. The low level between passages 372 and 409 occurred in a period when the concentration of iron had been reduced as a result of experiments later shown to have been misinterpreted[82]. The sudden fall in passage 425 resulted from the accidental omission of iron from one batch of nutrient. Other fluctuations are, however, unexplained.

The clone is still in excellent condition and shows every evidence of potential immortality. Cultures of this stock have been sent to the University of Missouri, the California Institute of Technology, New York University and Connecticut College, where they have been maintained through various periods, for special studies and for comparison with other clones of tomato roots.

Since this note is chiefly historical in import, I have appended a chronological bibliography of all papers dealing with the cultivation of excised root tips that have come to my attention, which gives, better than could any but a very extended discussion, a panoramic view of the development of this branch of plant tissue culture. I have purposely omitted references dealing exclusively with the cultivation of other tissues or organs, except for a few of the very early background papers, since these represent a separate though closely related field.

THE ROTHAMSTED CENTENARY

IN spite of the difficulties arising out of the War, a impressive gathering assembled at Rothamsted o July 21 to take part in the commemoration of it hundred years of uninterrupted work in agricultura science. There have been several similar occasions i the history of the Station, when the leading figure in the agricultural world have been glad to testify t the value of its activities. The first was in 1855 when a new laboratory building was formally hande over to Lawes and Gilbert as a testimonial from British farmers in recognition of twelve years pioneering work. The second was the jubilee of the Rothamsted Experiments, celebrated in 1893, when th experiments, having completed fifty years, had lef their mark not only on home farming but also on settle agriculture over a much wider area. Now, after th passage of a further fifty years, we were witnessing another ceremony—not, of course, on the international scale which would have been appropriat in normal times, but none the less a very outstanding demonstration of the high regard in which the pas and present work of the Station is held in scientifi and agricultural circles. Lord Radnor, chairman o the Lawes Agricultural Trust, presided, and th Right Hon. R. S. Hudson, Minister of Agriculture received a special welcome from the three hundre guests representing various scientific societies and al sides of the agricultural and allied industries. Representatives, diplomatic, scientific and agricultural from twenty-eight countries were present.

Welcoming the guests, Lord Radnor recalled som of the main facts in the history and achievement o the Station, and said that the completion of the firs century of work coincided with the coming retirement of Sir John Russell and the appointment o Dr. W. G. Ogg, of the Macaulay Institute of Soi Research, Aberdeen, as director. In his speech, th Minister of Agriculture pointed out how the prope use of fertilizers so firmly based on Rothamsted worl from its earliest days is now more than ever essentia in the food production campaign. He gave as a example the key position of superphosphate—th first great practical outcome of Lawes' experiments—

in the present need to establish new grass on worn-out plough land, and bring poor pasture into productive arable cropping. Fortunately, owing to the Allied victories in North Africa, the supply of this essential requirement is improving, for cargoes of phosphate rock are now coming in. He was pleased to find that, thanks to the practical example presented by land managed by war agricultural committees, farmers are more ready to adopt new methods than they have ever been. In conclusion, the Minister congratulated Sir John Russell on his well-earned retirement and expressed his hope that Rothamsted would long continue its work in fundamental agricultural research.

Sir John Russell then gave his director's address. Remarking that it was the last time that he would address an annual gathering in his present capacity, much of his speech dealt with the way in which Rothamsted fits into the general pattern of agricultural research and education in Great Britain. The function of Rothamsted, he said, is the development of a sound, trustworthy science of plant growth for the use of experts, teachers and farmers. Once the scientific principles are definitely established, the local organization can proceed to apply them to the solution of immediate practical problems—a vitally important task in modern agriculture, the success of which is limited by the amount and value of the scientific knowledge available.

The remainder of the programme was designed to give a view of the extensive and excellent modern equipment of the laboratories and farm against the background of the early history and continuity of the famous experiments. The visitors were conducted through the laboratories, where each department had arranged exhibits to illustrate important results, and special apparatus such as the electron microscope and polarograph. To amplify the necessarily short demonstrations, a comprehensive summary of the work of every department was distributed in booklet form. A recent account of the botanical investigations appeared in NATURE of July 24, p. 91. In the main hall was a collection of prints and original letters which recalled the earliest days of the Station, when the experiments were conducted in the old barn laboratory and the Lawes-Leibig controversy was in its bitterest phase.

The tour round the farm was made over a course that could be followed by tractor-drawn trailers on which the visitors were accommodated. Owing to the large company, loud speakers were called into service for the first time. Broadbalk, carrying its hundredth successive wheat crop, was the central attraction of the tour, and this year the field had risen to the occasion and produced a crop well above average. Thanks to the trailers, many visitors obtained a better view of the modern field work of the Station than ever before, for they saw many factorial plot arrangements testing problems of immediate practical importance: the substitution of potash by salt for sugar beet and barley, the utilization of sewage sludges and compost, manurial trials on flax, to mention only a few. Long-term work involving the study of slow changes in the soil was represented by rotation experiments on the utilization of straw. One of the most interesting exhibits in the farm buildings was the special equipment used at Rothamsted for laying out, harvesting, and threshing the field experiments.

The impression given by this visit to Rothamsted on its hundredth birthday was not one of age, but rather of abounding vitality. H. V. GARNER.

NEWS and VIEWS

Scientific Research in Great Britain

IN a debate on scientific research in the House of Lords on July 15, Viscount Samuel urged the need for further expansion of scientific research, particularly in relation to the utilization of coal. After stressing the need for research in all branches of science relating to food and agriculture, in nutrition, in building, in town and country planning and in the social sciences, he referred to the emphasis laid on research in the report of the Coal Industry Commission in 1925-26, and asked for an indication as to the Government's future plans for the expansion of research into all branches of the fuel and power industries. Lord Samuel mentioned the importance of giving the scientific worker himself proper status and the opportunity of advancement to administrative appointments when he possesses administrative ability, and asked whether there is any plan for allocating the work of scientific research between the three main agencies now engaged in it, namely, the State, the universities and the industries. Secondly, he asked whether anything could be said at this stage with regard to the conditions of employment of those engaged in scientific research, and whether there is any possibility of a combined scheme for pensions which would enable accrued pension rights to be transferred if a worker passes from one institution to another. Next, he inquired whether there is any prospect of a State scientific service being established parallel to the Civil Service and under the general direction of a commission like the Civil Service Commission but containing professional men of science. Finally, he again raised the question of the advisability, after the War, of appointing scientific attachés to the principal British Embassies abroad.

In supporting Lord Samuel's motion, the Earl of Listowel suggested that the Government programme to guarantee our industrial future should promote a gradual but steady increase in existing facilities for scientific research into the post-war problems of industry, an expansion including the research workers and the scientific equipment of universities, private firms and Government institutions. Secondly, to prevent overlapping and to secure the right priorities, these extended facilities should be co-ordinated and developed according to a national plan for scientific research. Lastly, it should arrange for consultation and co-operation with the Dominions and Colonies and with others of the United Nations. Lord McGowan welcomed the Government grant of £5,000,000 for research on coal, but considers that that sum will be found quite inadequate. Speaking of science in relation to industry generally, he urged that if we wish to hold and increase our export trade, there must be intensive research to find new processes and new products. Research on existing processes is day-to-day work, never ending, and accumulated knowledge creates of its own accord considerable industrial advances. Fundamental research is more a function of the universities. There is still much to be done in extending scientific academic facilities, and while this is a great opportunity for Government assistance, industry has also a big part to play, and he pleaded that industry should assist by financial grants. Lord Brabazon warmly applauded the work of scientific men in Great Britain. He also referred to the need for scientific men who could bring together and correlate the knowledge of different branches of science.

The debate was resumed on July 20, and Lord Cherwell, replying for the Government, reviewed the question of Government intervention in research. Admitting that in the last decade emphasis had tended rather away from fundamental research to the industrial side, he said that the whole distribution of effort is now being reviewed, and he hoped that it would be agreed to extend considerably Government support of pure scientific research. It is extremely difficult to make people realize the importance of fundamental scientific research and its value to the community, but even from the economic point of view we cannot overrate the importance of fostering such research. While that must be in large measure the responsibility of the Government and carried out at the universities, the Government also wishes to encourage industry to spend money on pure research. It is the policy and intention of the Government to increase the assistance given to pure research, but any similar developments in industry would be welcomed. Lord Cherwell welcomed a reference made to training in science, and said that the Board of Education is conscious much remains to be done in this field and is anxious to develop it as part of its policy for post-war reconstruction. Frankly admitting that the Civil Service has not hitherto shown due regard for the contribution which men of science are making to the nation's welfare, he stated that an investigation has been in progress to make sure that the conditions of service, pay and prospects of Government scientific employees compare favourably with those on the administrative side so that, among other things, interchange might be made easier, and he hoped that a definite announcement that these reforms are to be put into effect would be made before long. In welcoming this statement, Lord Winster expressed the view that when the history of Mr. Churchill's administration came to be written, it would contain a chapter on what has been done for the encouragement of science in Government Departments that would reflect the greatest credit on the Prime Minister.

A Pioneer of the Rubber Industry

On July 25 occurred the centenary of the death of the Scottish chemist Charles Macintosh, whose name is now a household word through his discovery of how to render cloth waterproof by cementing two layers of fabric together with a solution of rubber in naphtha. His patent for the process was taken out in June 1823, and at the works he established at Manchester the first "Waterproof Double Textures" were manufactured. His work was contemporary with that of Thomas Hancock (1786–1865), who for many years was his collaborator and partner. Together they firmly established the rubber industry in Great Britain. To Hancock also belongs the credit for the introduction of the 'vulcanization' of rubber, but he was led to the discovery of this process through experiments made after receiving a piece of rubber which had been subject to the process of 'solarization' by Charles Goodyear (1800–60) in America.

Macintosh was the son of a practical chemist and was born in Glasgow on December 29, 1766. As a youth he attended the lectures of Black at Edinburgh, and at the age of twenty began manufacturing sal ammoniac. He started the first alum works in Scotland, and for a time was associated with Charles Tennant of the St. Rollox works in Glasgow. He travelled a good deal on the Continent and was known to most of the principal chemists of his day. Among his friends was James Beaumont Neilson, F.R.S., the first engineer of the Glasgow gas works and the inventor of the 'hot blast'. In 1819 Macintosh engaged to take all the tar and ammoniacal liquor—then waste products—from the gas works, and it was in his treatment of the tar that he obtained naphtha, which he found could be used to make waterproof varnishes.

Royal Society of Edinburgh: Robert Cormack Bequest

The Royal Society of Edinburgh has been made the residuary legatee of the estate of Mr. Robert Cormack, of Edinburgh, who died on August 13, 1942. The Society is directed to administer this bequest for the purpose of promoting astronomical knowledge and research in Scotland, so far as practicable, on the lines of a memorandum prepared in 1931 by the late Prof. R. A. Sampson, Astronomer Royal for Scotland. The Council, on behalf of the Royal Society of Edinburgh, has accepted the bequest, which represents an amount somewhat over £30,000; and, after careful consideration, has approved a general scheme for the administration of the Trust, which will include: (*a*) research fellowships to be awarded on suitable conditions to students engaged on research in Scottish observatories and to students or graduates of Scottish universities desirous of engaging in research in foreign or Dominion observatories; (*b*) the publication of the results of such research; (*c*) lectures to be delivered in suitable centres by eminent foreign or Dominion astronomers; (*d*) grants in aid of the purchase of special equipment for use in Scottish universities or observatories in research work; (*e*) lectures and demonstrations of a more popular character under the auspices of the Scottish educational institutions. A large part of this scheme will not be developed during the War.

Fleas of North America

Under the foregoing title, H. E. Ewing and Irvine Fox have written a taxonomic revision of the North American Siphonaptera. Such diseases as bubonic plague and a mild form of typhus are carried to man by the agency of these insects, which also play an important part as pests of livestock, etc. The matter of correctly identifying fleas assumes, therefore, considerable importance, and the present work will aid those engaged in such procedure. Full descriptions are given of the genera and higher groups, and are accompanied, for the most part, by illustrations of diagnostic characters. Formal descriptions of species and subspecies are avoided and, instead, remarks on characteristic features are given. The paper is issued as Miscellaneous Publication No. 500 of the U.S. Department of Agriculture

(1943), and in it are listed 61 genera and 209 species of fleas from North America and the West Indies. In discussing the relationships of the Siphonaptera the authors take the view that they are derived along with the Diptera from a common ancestral stock. They regard fleas as being more ancient and more primitive than Diptera and classify them into six families. Owing to synonymic changes several of the names thus used will be unfamiliar to non-specialists. At the end of the paper is a very complete bibliography which takes into account the literature on these insects up to October 1940. A careful revisional paper of this kind is of wider interest than to North American workers only, and it is commended to the attention of students in Britain also.

Rubber-yielding Dandelions in Sweden

ACCORDING to the June issue of the *Anglo-Swedish Review* the scarcity of rubber in Sweden forced that country to evolve substitute products. The experimental production of synthetic rubber has been going on for some time, and its manufacture on a commercial scale has been commenced by a number of companies. Side-by-side with the work attempts are being made to cultivate rubber-yielding dandelions of the Russian type (*Taraxacum kok-saghyz*). Cultivation on a small scale started last year and this year it will be possible to extend somewhat the sown area by means of seed obtained from these cultivations. It is estimated that by the end of 1944 Sweden will have at its disposal about 300 kilograms of seed and a crop of about 27,000 kilograms of one-year old root and 38,000 kilograms of two-year old root in addition to a sown area of 230 hectares. The rubber content in the one-year old root is estimated at 2 per cent and in the two-year old root at 3 per cent. The rubber obtainable from this crop will be very insignificant, but enough for further experiments to ascertain the quality of this rubber and its susceptibility for various purposes.

Future of Technical Colleges

Messrs. R. M. Barrer and J. P. Andrews have written in connexion with their letter in NATURE of July 17, p. 80, on this subject. The phrase "relieve the Technical Colleges of the necessity of preparing students for External University Degree" appearing in quotation marks implies that it was quoted from the report of the Board of the Institute of Physics. This is not the case, so quotation marks should not have been used.

The Night Sky in August

NEW moon occurs on August 1d. 04h. 06m. U.T. and full moon on August 15d. 19h. 34m. New moon occurs again on August 30d. 19h. 59m. The following conjunctions with the moon take place: August 2d. 05h., Mercury 0·5° N.; August 4d. 08h., Venus 7° S.; August 22d. 16h., Mars 4° N.; August 24d. 18h., Saturn 3° N.; August 28d. 21h., Jupiter 0·9° N. The following occultations of stars brighter than magnitude 6 occur: August 12d. 21h. 38·9m., 121 B. Sgr (*D*); August 20d. 23h. 09·4m., ξ^2 Cet (*R*); August 23d. 03h. 02·0m., γ Tau (*D*); August 23d. 04h. 09·7m., γ Tau (*R*); August 23d. 12h. 36·8m., ϵ Tau (*D*). The times are given for Greenwich, and *D* and *R* refer to disappearance and reappearance respectively. Mercury is an evening star, reaching its greatest eastern elongation on August 29, on which day it sets at 19h. 23m. At the beginning of the month it sets about 20 minutes after sunset. Venus is stationary on August 13 and sets at 19h. 50m. on that day. At the beginning and end of the month the planet sets at 20h. 45m. and 18h. 10m. respectively and is visible as an evening star during the first part of August. Mars moves from the constellation of Aries to Taurus early in August. The planet can be seen as a morning star and rises at 23h. and 21h. 50m. at the beginning and end of the month respectively. Jupiter is too close to the sun to be observed in the early part of the month. At the end of the month the planet rises at 3h. and sets nearly an hour before sunset. Saturn, in the constellation of Taurus, is a morning star and rises at 1h. and 23h. at the beginning and end of the month respectively. Times are given approximately for the latitude of Greenwich. In addition to the phenomena mentioned above, the following take place: August 4d. 17h., Mercury in conjunction with Regulus, Mercury 0·8° N.; August 17d. 07h., Mercury in conjunction with Venus, Mercury 6·1° N. The Perseid meteors will attain their maximum on August 10–12, but moonlight will interfere with the observations until midnight.

Eclipses. There will be an annular eclipse of the sun on August 1, invisible at Greenwich. It will be visible as a partial eclipse in Australia and its magnitude will be 0·69 at Melbourne, where it will commence and end at 4h. 02m. and 6h. 54m. respectively. A partial eclipse of the moon will take place on August 15 and will be partly visible at Greenwich. The beginning will be visible generally in the western part of the Pacific Ocean, Antarctica, Australia, New Zealand, the Indian Ocean, Asia, south-eastern Europe and Africa, except the north-eastern part. The circumstances of the eclipse are given below:

Moon enters penumbra	Aug. 15d.	16h.	58·0m.
,, ,, umbra	15	17	58·5
Middle of Eclipse	15	19	28·4
Moon leaves umbra	15	20	58·1
,, ,, penumbra	15	21	58·3

Announcements

THE University of Oxford has conferred the honorary degree of D.Litt. on Prof. A. L. Bowley, acting director of the University of Oxford Institute of Statistics.

THE University of Leeds is to confer the following honorary degrees: *LL.D.*, Prof. H. S. Raper, Brackenbury professor of physiology in the University of Manchester; *D.Sc.*, Mr. E. V. Evans, chairman of the Gas Research Board.

AT the recent annual meeting of the Royal Society of New South Wales, it was announced that the Council has awarded the Clarke Memorial Medal for 1942 to Dr. W. L. Waterhouse of the University of Sydney in recognition of outstanding contributions in the sphere of natural science, particularly in plant pathology.

AT the annual general meeting of the Institute of Physics held on July 22, the following were elected to take office on October 1: *President*, Sir Frank Smith; *Vice-Presidents*, Mr. E. R. Davies, Dr. W. Makower and Mr. T. Smith; *Honorary Treasurer*, Major C. E. S. Phillips; *Honorary Secretary*, Prof. J. A. Crowther; *Ordinary Members of the Board*, Prof. J. D. Cockcroft, Mr. D. C. Gall, Dr. H. Lowery, Mr. D. A. Oliver, Mr. A. J. Philpot, and Mr. R. S. Whipple.

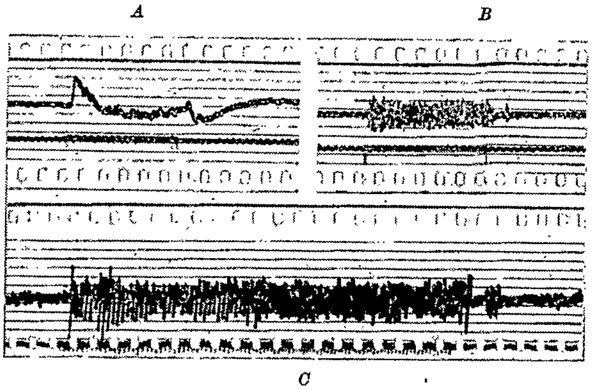
Electrical Responses from the Primary Acoustic Centre of the Frog

It has been shown that sound stimuli elicit electrical potential changes in the central auditory pathways in the cat[1,2]. We have studied these responses in the frog, using micro-electrodes, which permit of a more detailed picture in respect of at least some of the electrical phenomena.

The roofs of the skulls of isolated heads of *Rana temporaria* were removed and the preparations placed on cotton wool soaked in Ringer's solution. Potential changes were led off from the acoustic area in the dorso-latero-cranial part of the bulb by means of an isolated tungsten micro-electrode and an Ag-AgCl-electrode placed on the cotton wool bed, and led to a capacity-coupled 4-stage amplifier operating a cathode ray oscillograph, from which the deflexions were photographically recorded. Controls were made on the dead brain to show that no disturbing artefacts occurred.



A. Micro-electrode on the acoustic area of the frog. Higher frequencies not recorded. "On" and "off" effect at the beginning and after the stimulus, marked on the lower line. Time 1/50 sec. *B*. Impulses led off from the same spot, high frequencies recorded. Note the second group of impulses during the "off" effect. C. Same as 1 *B* but higher amplification, micro-electrode on a different spot. Sound stimulus 200/sec.

The curves obtained with the micro-electrode placed in the most superficial cell layers of the acoustic area revealed a certain amount of spontaneous activity (Fig. *C*), confirming previous findings[3]. The discharge was of a low voltage (5–15 μV.) but clearly distinguishable from the noise-level. Sound stimuli, produced by a loud-speaker, fed from a neon lamp oscillatory device, elicited typical changes in the picture, though the area from which these responses could be obtained was rather small. With the use of a frequency filter and a time constant of the amplifier of the order of two seconds it was possible to record slow waves at the beginning and immediately after the conclusion of the stimulus, appearing as 'on' and 'off' effects. Effects of this kind are shown in Fig. *A*. The latent period for the appearance of the first spike-like deflexion was 20–40 m.sec. The 'on' and 'off' effects were always of opposite signs and, in our arrangement, had an amplitude of up to 100 μV. When the amplifier was tuned for higher frequencies a sudden outburst of impulses in rapid succession occurred at the onset of the sound stimulus, and lasted slightly longer than the latter. During the 'off' effect a definite inhibition of the discharge could be observed. This was more distinctly borne out by curves recording the train of spikes when the amplifier was working with a short time constant, as illustrated in Fig. *C*. The spikes started after a latency period of 20–30 m.sec. corresponding to the appearance of the 'on' effect. The amplitude of the spikes remained practically unaltered during the stimulus, if this lasted less than 2 sec., but usually became gradually less during longer stimuli. As to the frequency of the spikes, it corresponded closely to the frequency of the sound stimulus, within the range studied in the preliminary experiments (200–500 cycles). A similar correspondence has been described previously for the acoustic nerve[1]. That the effect is not a microphonic one was shown by the latent period and by the 'off' effects described below. The 'spikes' shown in Fig. *C* do not seem to represent the activity of single fibres, since it has been found that the amplitude varies with the intensity of the stimulation. It therefore seems more probable that they are built up by the simultaneous activity of a group of fibres.

At the end of the stimulus the impulses continued for about 50 m.sec. at a diminishing amplitude. After this a short silent period ensued, followed by a short, but very distinct volley of spikes, lasting a few hundredths of a second and of about the same frequency as during the preceding discharge. After this volley the spontaneous activity was usually markedly reduced for some 50–100 m.sec. When slow waves only were recorded, as in Fig. *A*, a few waves occurred during the 'off' effect, which seem to correspond to the volley of spikes described above. The silent period and the secondary volley of spikes were usually well marked after short stimuli (about 1 sec.) but may be absent after stimuli of 10–30 m.sec. duration. There was no evident correlation between the duration of the stimulus and the amplitude of the 'off' wave. The latter, however, like the other effects described, is correlated with the intensity of the stimulus.

Relation between Experiments on Isolated Muscle and Isolated Strips of Myosin

Astbury and Dickinson[1] have shown that isolated strips of myosin from unstriated muscle show thermal contraction below 40° C. It is interesting to note that living muscle also begins to show increased tone at this temperature[2,3]. The effect of alkalis is to increase the contraction of myosin; in actual muscle tone is increased in alkaline solutions[4–7].

These observations are interesting in view of the elation between isolated, dead myosin and that of ving muscle, and also because of their bearing on he nature of muscular contraction. A substance ay act directly on the contractile mechanism of the uscle, or indirectly through the excitability system. f any agency affect myosin and muscle identically, hen it acts on the contractile mechanism directly, hough it may also affect the excitability mechanism. rise in temperature will directly affect the conractile mechanism.

Contraction of myosin and of muscle under similar onditions suggests the possibility of muscular conractions without oxygen consumption. When untriated muscle is immersed in solutions containing arium chloride, a reversible contraction occurs hich persists when the muscle dies[8]. This contraction s not accompanied by an increase in oxygen conumption[2]. Barium chloride solutions do not harm he muscle, which may remain alive in such an nvironment for several hours. The persistence of he contraction after death of the muscle is noteorthy.

If the normal contraction of muscle be due to the ontraction of myosin molecules, then the internal riction between molecules would increase when the muscle contracts[5] and the viscosity of muscle would hus increase. Gasser and Hill[9] found that the iscosity of striated muscle increases during conraction. Such increase in viscosity should then be bolished by stretching, which should undo the intramolecular transformation. In Mytilus muscle, stretchng decreases viscosity, as shown by its effect on the ate of change of length[5,3,2]. It is generally considered hat unstriated muscle, which is usually tonically ontracted, is more viscous than striated muscle.

The question then arises as to why in one type of ontraction there is an increase in oxygen consumpion and not in the other. It might be suggested hat, when accompanied by an increase in oxygen sage, contraction is maintained by an unstable metabolite, which, by combining with myosin, induces attraction between component parts. When nstriated muscle contracts without increase in oxygen consumption, distortion of the myosin molecule may cause attractive forces to come into play without any intervening agency.

When unstriated muscle is immersed in sucrose or glucose solution, it contracts, but its oxygen consumption decreases[6,2]. When the muscle is reimmersed in Ringer solution, it relaxes and its oxygen consumption increases. In this connexion it is interesting to note that the oxygen consumption of isolated unstriated muscle, which is usually found in a state of tonic contraction, is less than that of isolated striated muscle, which is usually relaxed.

A Modification of the Gemmell Single Cyst Technique for the Potato Strain of the Eelworm *Heterodera schachtii* Schmidt

THERE is little doubt that the single cyst technique recently described by Gemmell[1] is a considerable advance on methods previously used in work with the potato strain of the eelworm *Heterodera schachtii*. As it is probable that the method will eventually be widely used, it was thought worth while to describe a simple modification of the method which, it is thought, possesses certain advantages over the original.

In the Gemmell technique, each cyst is kept in a single drop of potato root excretion on a cover-slip which rests on a glass ring standing in a Petri dish. The drops of excretion are prevented from evaporating by a sheet of moist filter paper lining the floor of the Petri dish, and half-inch diameter holes, on which the glass rings stand, are punched in the paper so that counts of the larvæ can be made by observation through the clear areas; when counts are made, the under surface of the cover-slip has to be wiped to remove condensed moisture, and the slip is then replaced on the glass ring. Each 12 cm. petri dish accommodates five cysts. Clearly, the examination of several hundred cysts involves considerable manipulation; the following method is much more economical of labour, and, incidentally, of glassware too.

Circles are 'stamped' on a Petri dish by means of a half-inch diameter ring first dipped into melted 'Vaseline'; a single cyst and a drop of root excretion are added to each circle, as in the Gemmell technique, but the chamber is kept moist by filter paper adhering to the *lid* of the Petri dish. The advantages of this method are: (1) 25 cysts are easily accommodated in a single 12 cm. Petri dish and larval counts are therefore easier; (2) the problem of moisture condensation is eliminated.

Gemmell transfers each cyst to another cover-slip after each larval count; it is doubtful if this is really necessary, at least with the modified technique, for the larvæ can be removed with certainty with a bent pipette, and fresh root excretion added. The 'Vaseline' circles are easily made, and, in contact with root excretion, they retain their sharp outline for weeks. Paraffin wax can be used instead of 'Vaseline', but the latter is more easily used owing to its lower melting point.

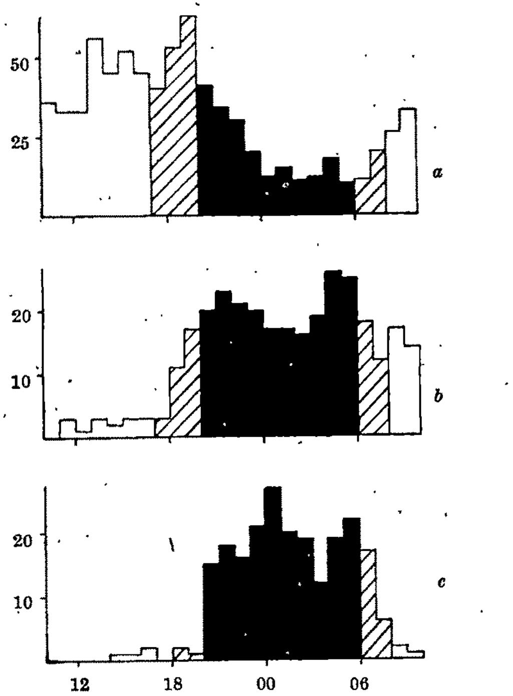
Diurnal Activity of Three Insect Pests of Stored Products

I WAS recently enabled, through the kindness of the mill staff, to carry out a series of observations over a 24-hour period in a certain flour mill. The mill contained bags of infested spaghetti which had been stacked up in preparation for fumigation. The stacking was done three days before the observations were made, and it was assumed that any disturbing effect of moving the bags during stacking had died down.

The animals dealt with were *Ephestia kühniella* Zell. larvæ, *Ptinus tectus* Boie. adults and *Calandra granaria* L. adults. The observations consisted of hourly counts of the numbers of animals active on the surface of a certain area of the spaghetti bags. An electric torch was used for observing the animals, and it was allowed to play on them for as short a time as possible, so as to minimize its disturbing effect. During the mill's working hours, 8 a.m.–5 p.m., electric lighting was on, which together with daylight coming in from open doors gave dim light. Some machinery was in action, causing a certain amount of vibration. Readings of temperature and relative humidity were made directly after each count. The temperature only varied from 11·5 to 12·5° C., while the humidity was between 70 and 80 per cent throughout.



DIURNAL ACTIVITY OF (*a*) *Ephestia kühniella*, (*b*) *Calandra granaria* AND (*c*) *Ptinus tectus*. ORDINATES, NUMBERS OF ANIMALS ACTIVE; ABSCISSÆ, TIME B.S.T. BLACK-OUT PERIOD IS SHOWN IN BLACK; PERIOD BETWEEN BLACK-OUT AND MILL WORKING HOURS IS SHADED.

The results are shown in the accompanying figure. Those for *Ptinus tectus* confirm in "the field" results obtained by Bentley *et al.*[1] in laboratory conditions. *Calandra granaria* shows a similar pattern of activity. In *Ephestia kühniella* the reverse pattern is shown, activity being greatest during the daytime. In Ptinus and Calandra activity and exposure are parallel; during the day-time when the animals are inactive they are hidden away in cracks, under bags, etc. The reverse is true for Ephestia larvæ; during the night, when activity is least, many animals are exposed. They lie motionless on the surface of the bags, and are easily visible. The largest number of caterpillars, counting both active and inactive, was seen exposed on the surface of the bags shortly after dusk.

From casual observations in various parts of the mill throughout the night it was clear that the following species are also more exposed during the night: *Tenebrio molitor* L. (larvæ), *Oryzœphil* *surinamensis* L. (adults), *Ptinus tectus* Boie. (larvæ *Ephestia kühniella* Zell. (adults), *Lyctocoris campestr* F. (adults and nymphs).

These observations confirm the impression gene ally held that insects in stored products are mo obvious by night than by day. This is true not onl for those which show greatest locomotory activit by night, but also for caterpillars of *Ephestia kühniell*

Tablet Absorption and Ghost Formation

THE formation of ghosts in compressed tablets o synthetic œstrogens during subcutaneous implantation has been previously described[1]. These structure are probably composed mainly of scleroprotein forme by a reaction between the synthetic œstrogen an soluble protein in the tissue fluid. The phenomenon ha also been observed in tablets of œstrone, œstradiol an pregneninolone in the human[2] and in a tablet o testosterone propionate in a bull. It has since bee found that ghosts are formed *in vitro* in hexœstro tablets incubated in blood serum and plasma and i aqueous solutions of various proteins.

Further absorption studies with compressed tablet of pure hexœstrol, carried out primarily with th object of elucidating the role of ghost formation i tablet absorption, have led to the following conclusions.

Compressed hexœstrol tablets, of the type used possess a labile fraction (that may or may not b located in the surface zone) which is quickly lost o subcutaneous implantation or incubation with bloo plasma or with distilled water. The remaining portio is much less soluble. It was reported previously[3] tha tablets re-implanted subcutaneously after a previou *in vivo* implantation undergo less absorption in a give time than unused tablets. It has now been found tha this also applies to tablets which have been incubate in blood plasma, and, what is most significant, in distilled water. It thus seems that the reduced initia absorption on re-implantation must be due to th loss of the labile fraction during the previous implantation and not, as was once believed[3], to th presence of a pre-formed ghost in the tablet.

In consequence of the labile fraction, absorptio curves for 1,000 mgm., 500 mgm. and 250 mgm tablets in the bovine, goat, rabbit, rat, guinea pi and pigeon show two phases. There is an initia phase of rapid absorption, after which the curve bend sharply and absorption proceeds at a linear but reduced, rate. The linear section of such a curv makes, on extrapolation, a positive intercept on th vertical (absorption) axis, from which the weight o the labile fraction may be estimated. On the othe hand, curves for 50 mgm., 25 mgm. and 15 mgm tablets in the rat are linear and pass through, or ver near, the origin.

Because of ghost formation, apparent absorptio values, determined by weighing tablets before an after implantation, are in all cases lower by th weight of the ghost than the true values. On extrapolation, therefore, true absorption curves mak larger intercepts on the vertical axis than appare urves. The true absorption curves for small tablets 1 the rat are thus probably of the same form as ose for larger tablets, though here the difference ade by the ghost correction has been found to be uch less than for large tablets. Even after applica ion of the ghost correction, such curves make only mall intercepts on the vertical axis, indicating that or reasons at present unknown, the labile fraction is ss important in the smaller classes of tablet than in ablets weighing 250 mgm. and upwards.

The characteristic absorption rate for tablets of ny given weight is represented by the slope of the bsorption curve during the linear phase. Absorption ates per mm.^{2} of tablet surface, for tablets of various izes implanted in different animals, were approxi nately constant, provided that the tablets were not oo large in relation to the size of the animal, showing hat absorption rate is proportional to surface area. n the rat, the linear absorption rate of large tablets vas found to be either very much reduced (500 mgm. ablets) or zero (1,000 mgm. tablets), possibly because of saturation of the body fluids or local tissues with exœstrol absorbed during the initial phase.

These experiments, which will be more fully lescribed elsewhere, show that ghost formation is not esponsible for the fall in absorption rate observed vith large tablets shortly after implantation, but provide no answer to the question whether or not he presence of the ghost has any influence on the inear absorption rate.

Propagation of Potato Seed Tubers from Stems

MENTION has been made by Dr. N. Polunin[1] of he practice of propagation of potatoes for seed ubers from what are described as 'tops'. This work as been developed in the U.S.S.R. recently by Prof. Lysenko. The method was employed in Great Britain during the War of 1914–18, though on a smaller scale. The term 'tops' has caused some con fusion among British workers, for it refers to the severed rose or top ends of large-size tubers and not, as might be supposed, to the aerial stems of the plant. Tops, shaws or haulms are common names in Great Britain for the stems and thus a wrong impression has arisen.

Propagation for seed tubers is possible, however, from pieces of the aerial stems, and my observations are given below because they may be of value where there is a critical need for the largest quantity possible of seed tubers, as in the U.S.S.R. It is also desirable for breeders of potatoes to multiply the stocks of a new and valuable variety at as great a rate as possible without causing any deterioration in vigour.

When early varieties such as Arran Pilot are lifted, in June or early July, the strongest and healthiest stems are collected and treated in the following manner. The roots and the tip ends are cut off with a sharp knife, the leaves are also stripped by the same means, but any small axillary shoots are left. The stem is then cut transversely into two separate halves, so that each half possesses not less than three nodes. If these stem pieces are planted in moist soil at a depth of about 5–7 cm. they will give rise to small plants and to a crop of seed-size tubers before winter. The stem pieces are, however, susceptible to attacks by slugs and should be treated with a suitable deterrent where these pests are present.

In the course of this work it is observed that, if the axillary shoots are removed or if they are very minute, small tubers of a perfectly normal appearance develop in the axils in about ten days. This occurs not only in the soil but also where the stem pieces are left in the dark, in boxes and in a cellar preferably covered by damp sand or moss. Growth is continuing after three weeks and there is reason to suppose that the majority of the tubers will reach the size of chats, which are often planted in the field in Great Britain.

This latter method presents possibilities for the propagation of second early and maincrop varieties, where it is too late in the season, when they are lifted, for the stems to be replanted in the earth. Darkness appears to be essential to normal tuber formation and it is necessary to avoid any place which is too damp and badly ventilated or, on the other hand, too dry. The former condition may cause rotting and the latter a shrivelling of the stem piece.

Investigations are still in progress, but it is desirable that the matter should be made known before the present season is too far advanced for others to try these methods.

Distribution of Catalytically Active Centres on Surfaces

THE autopoisoning of catalytically active copper in dehydrogenating ethyl alcohol above 280° C., previously reported[1], has been further studied. Assuming a linear law of variation of the velocity constant k_ε of the poisoning with the heat of activation ε on the distribution[2] of centres of activity on the surface over the narrow range of values of ε which determine the reaction velocity in the form

$$k_\varepsilon = k_0 (a + b[\varepsilon - \varepsilon_1]),$$

where ε_1 is the lower limit of the value of the heat of activation, the equation for the decay of reaction velocity with time in the auto-poisoning of the distribution of active centres becomes

$$v_t = v_0 \ \frac{e^{-at}}{1 + \beta t},$$

where $\frac{\beta}{\alpha} = \frac{b}{a\lambda}$, and λ is the exponential factor giving the decrease in the reactivity of centres with heat of activation as the heat of activation rises over the distribution.

Now $\lambda = \frac{1}{RT} - \frac{1}{h}$, or according to Cremer and Schwab[3], $\lambda = \frac{1}{RT} - \frac{1}{RT_e}$, where T is the absolute temperature of reaction, and T_e is the absolute temperature at which the groups of atoms with strong external fields are frozen in equilibrium. Thus

$$\frac{\beta}{\alpha} = \frac{b}{a\left(\frac{1}{RT} - \frac{1}{h}\right)} = \frac{bR\,TT_e}{a(T_e - T)},$$

giving in the region of temperature below T_e, provided $\frac{b}{a}T$ does not change appreciably, that $\frac{\beta}{a}$ $(T_e - T)$, that is, β/α multiplied by the difference in centigrade temperatures, should be approximately constant, or that the ratio should rise rapidly on approaching the apparent temperature at which the groupings of atoms have been frozen.

Measurements of the rate of dehydrogenation in this region have given the following preliminary results :

(*a*) the formula fits the curves reasonably closely ;

(*b*) both α and β and the ratio β/α rise as the temperature of reaction increases towards T_e ;

(*c*) the product $\frac{\beta}{a}$ $(425 - T°\ \text{C.})$ is approximately constant.

Temperature (T °C.)	$a/2{\cdot}3$	$\beta/2{\cdot}3$	β/a	$\frac{\beta}{a}(425 - T)$
300	0·00309	0·00524	1·73	216
350	0·00541	0·01648	3·04	228
365	0·01265	0·04505	3·56	214

The results are also suggestive in that the apparent rise in the heat of activation appears to be shown in the α and β constants themselves. The active surface in these experiments appears to have been frozen at a temperature of 425° C., which gives a value of $1/h = 7{\cdot}2 \times 10^{-4}$ in the formula

$$\delta n = Ae^{\varepsilon/h}\delta\varepsilon\,;$$

this compares with a mean value of $6{\cdot}6 \times 10^{-4}$ directly measured in previous experiments[2].

The positive sign of β in the results leads to the conclusion that the more active centres poison more slowly than the less active ones. Further work is proceeding, but it does appear that this is a rare case in which information about the distribution of active centres may be obtained from measurements of the decay of reaction velocity at a series of temperatures in the region below T_e.

I beg to acknowledge with thanks a grant from the Dixon Fund of the University of London. A full account will be published later.

Marine Biology in the West Indies

In his recent communication[1] in which he urges the establishment of biological research stations in the West Indies, Dr. V. J. Chapman has raised a matter of prime interest to all British biologists. My interests are in marine biology but, before proceeding to elaborate the arguments for the establishment of a centre of marine research in the West Indies, it may be stated in general that the ideal training of all biologists should include some experience of tropical conditions. This has long been recognized in the United States, where admittedly access to tropical regions has been easier. But in days when hundreds or thousands cross the Atlantic weekly by air, Great Britain is effectively little farther from the West Indies than are the northern and western areas of the United States. We are promised great colonial development after the War and this project of Dr. Chapman's, whereby the universities of Great Britain can co-operate in the prosecution of fundamental biological research in the West Indies (and, it ma be hoped, farther afield also), is one of the obviou ways in which this development may be furthered.

Marine biological research in the southern Nort Atlantic has suffered a considerable setback owin to the closing down of the two marine stations a Bermuda and the Tortugas. The former, it is hoped will be re-established after the War, but its obviou function is the study of the waters of the Gulf Strea and to act as a link between the oceanographica work at Woods Hole and at Plymouth. It is destine to be an important Anglo-American link and woul in no way fulfil the functions of, or in any wa compete with, a marine station in the West Indies.

With the abandonment by the Carnegie Institutio of its laboratory at the Tortugas there is now n centre of marine research in the Gulf of Mexico o in the Caribbean Sea. It is well known that, bu for the untimely death of Dr. A. G. Mayor, thi station would probably long ago have been transferred to some more accessible site. Dr. Mayo certainly hoped to see it transferred to Montego Ba in Jamaica (one of the sites suggested by Dr. Chapma in his letter). Whether the Carnegie Trustees hav any plans for the continuance of tropical marin research after the War remains to be seen ; but i is at least possible that they might be prepared t co-operate in the establishment of a station i Jamaica.

The possibilities of a tropical marine station readil accessible to British workers are great indeed. I was the common impression of all my colleagues o the Great Barrier Reef Expedition that our intensiv year of work, when we attempted in the time available to apply the methods of Plymouth and o Millport to the study of coral reefs, did little mor than reveal to us the endless diversity of problem that the conditions of tropical marine life present t the inquiring mind. The diversity of forms of life and often the size of individual species, are muc greater in tropical waters ; the speed of developmen and growth and the intensity of environmenta factors greater than in temperate seas.

It is hoped that after the War the Colonial Offic will establish a fisheries service. It will need station in the West Indies, but more than that i will want a centre for the training of fisheries officer for services elsewhere in the tropical Atlantic and i the Indian and Pacific Oceans also. Where bette than in the West Indies, where direct contact coul be maintained with the parent British institution a Plymouth and also with the British universities Moreover, a colonial fisheries officer is none th worse for some knowledge of the characteristics o the terrestrial fauna and flora of the tropics whic could be obtained from the land station which Dr Chapman also suggests should be established.

Strong support, it is felt, should come from Britis universities for this project. Here, at Bristol, we hav historical connexions with the West Indies an still retain the major part of its now diminished trade Although I write this letter in a purely privat capacity I am confident that any appeal made t the universities on this matter would find here particular welcome and response.

[1] NATURE, 152, 47 (1943).

EDUCATION AND TRAINING FOR ENGINEERS

ON March 19, 1942, a paper entitled "A Critical Review of Education and Training for Engineers" was read in London before the Institution of Electrical Engineers by Dr. A. P. M. Fleming. The paper was prepared by a sub-committee of the Post-War Planning Committee of the Institution, with Dr. Fleming as its chairman, and it received an extended notice in NATURE of May 2, 1942 (p. 482). Based on this paper and the subsequent discussions, a 22-page report on "Education and Training for Engineers" has now been issued by the Post-War Planning Committee with the authority of the Council of the Institution, with the expressed hope that it may be of assistance to those concerned in the problems of post-war reconstruction in Great Britain.

Dealing first with craftsmen and foremen, it may be said that there is general agreement on the need for measures which will lead to improvement in the status of the craftsman. To this end the following recommendations are made. More care should be exercised in the selection of entrants to craft training courses. This should be the responsibility of panels representing wider interests and experience than those of the employer alone. There should be a probationary period for all craft apprentices during which provision would be made for transfer to more suitable employment where necessary. The apprenticeship should commence with a period in a special apprentice workshop where the elements of the craft would be acquired under the guidance of experienced instructors. Where possible, these workshops should be a part of the industrial organization, but co-operation of the local technical colleges will be necessary where this is impracticable. Subsequent practical training should be organized, and definite responsibility for the training course should be accepted by each employer. Part-time day release should be granted for general education and for vocational instruction. The combination of workshop and classroom instruction should be organized on nationally recognized ines and a 'craftsman certificate' should be instituted. Subsequent part-time courses should be provided eading to certification for foremanship. The school-eaving age should be raised, and the full-time education received up to this age and the part-time education received afterwards should both be planned on as broad a basis as possible. Thus every facility would be afforded for development, not only in the craft or trade but also in the best use of leisure; and transfer to other types of work would be simplified for the man who so desires.

As to student apprentices, this title is intended to cover those whose practical training and technical education are combined on a part-time basis, who will become draughtsmen, designers, etc., and may attain some of the highest executive positions. For such it is recommended that organized schemes of practical training should be instituted, or participated in, by all employers of student apprentices, and that recognized national standards should be established. Part-time day release for study, both general and technical, should be compulsory, and this release should be for not less than one full day per week. Attention to technical matters at the expense of the study of broad scientific principles should not be permitted in the early stages of the course. Some part-time evening instruction should also be available, but this should not be made compulsory. The present schemes of Ordinary and Higher National Certificates should be continued and developed and should form an integral part of student apprenticeship. Consideration should be given to making teaching in technical schools, institutes and colleges more attractive as a profession. The facilities which are available for technical teachers to return to industry for short periods, to renew their industrial experience, should be extended. Technical teachers should receive instruction in the art of teaching.

For university trainees it is recommended that full-time university courses should be made available to anyone who has the ability to obtain full benefit from them. There must be no financial barrier to entry. Schemes similar to the present State bursary scheme should be implemented after the War, provision being made for increased transfer from National Certificate to university courses. University engineering schools should cease to treat all students as potential high-grade scientific or technical workers; those who are not should receive instruction in economics, law and social science in place of the more advanced technical instruction. It is the duty of the university to equip men for leadership and not merely to impart advanced technical and scientific knowledge. University engineering students should devote part of the two shorter vacation periods to tutorial classes and part of the longer vacation period to the acquisition of practical experience. A period of the order of one year should be spent in gaining experience of industry before proceeding from school to the university. All university engineering graduates should be given a course of practical training of a broad character.

Lastly, in respect of 'post-advanced' students it should be remarked that the professional engineer must acquire specialized knowledge of the branch of engineering in which he is engaged, and the university graduate must acquire practical experience before he is able to apply his academic knowledge usefully. To this end it is recommended that postgraduate work at universities should be further developed, and that 'post-advanced' courses of lectures by recognized authorities should be provided locally on specialized branches of engineering practice. Technical colleges should extend the provision of 'post-advanced' courses in such subjects as economics, workshop organization and management, industrial management and business practice. These and similar subjects should be studied when the student is sufficiently mature to appreciate them and is likely to be able to make use of them. This is particularly important in the training of men who have been selected as potential executives. Such men should also be afforded opportunities of acquiring experience in administration.

Subsequent to the above recommendations, the report presents the bases upon which they are made, these being as follows: an outline of the pre-war engineering education and training system for England and Wales, and the essential elements of a satisfactory post-war system, which latter embody vocational guidance and selection, training of engineers, training of craftsmen, and the selection and training of teachers.

In its concluding paragraph, the report strikes the real keynote of success, urging that "the progress of engineering—in fact that of any human activity—depends on personnel. It is therefore essential in the national interest to secure the proper recruitment and training of personnel for the engineering industry, not only for the higher professional ranks but also for every grade of worker. It should be a fundamental principle in dealing with engineering personnel to ensure that every individual is so trained that, whatever the work on which he is employed, he can give service in the most efficient manner possible".

SCIENCE IN SOVIET RUSSIA

In his account of "Science in Soviet Russia" in the Trueman Wood Lecture before the Royal Society of Arts on April 14, Mr. J. G. Crowther said that the place of science in Soviet philosophy is the most important motive in the development of science in the Soviet Union.

Reviewing the development of the new physical research institutes, Mr. Crowther pointed out that these were not built until the men to run them had already been trained. Following that of the Ukraine opened at Kharkov in 1930, others were founded at Dniepropetrovsk, Sverdlovsk, Tiflis and other centres. The existence of these new scientific institutes, especially in the east, has been of great importance during the present War. Sverdlovsk, for example, received important sections of the Soviet Academy of Sciences when Moscow was threatened. The new institutes have special lines of research appropriate to the needs of the locality. The Physico-Technical Institute at Kharkov had large research departments in high-tension physics and low-temperature physics. At Dniepropetrovsk and Sverdlovsk, special attention was given to metallurgy, the latter Institute serving the scientific needs of the metal industry of the Urals.

In the planned development of science in the U.S.S.R., Mr. Crowther said that at least as much importance is attached to human as to natural resources, and the founding of special institutes for men of outstanding ability has been a feature of it. In such planning, the importance of the Academy of Sciences has steadily increased and it is now directly responsible for this work to the Supreme Soviet. The Academy determines the general lines of scientific work in accordance with the needs of the State and possibilities in subjects and personalities. It sees that balanced attention is given to all sides of science, that no important branches are neglected and overlapping is reduced. Moreover, such planning is a mutual process of adjustment in which ideas flow equally from the top and the bottom.

The plan of research for 1943 is mainly directed to the improvement of war industries and armaments (see Nature, January 30, p. 129). Geologists and geographers are engaged on the exploration and study of new sources of oil, ores and minerals, especially in the Urals, West Siberia, Kazakhstan and the Middle Volga regions. Agricultural science will be devoted to efforts to increase the yield of cereal and industrial crops such as rubber-bearing plants, potatoes and beet. Technologists are to develop the use of industrial gas and the gasification of new forms of fuel, so that local fuels can be utilized and long hauls reduced, in addition to research on aircraft, radio, weapons, etc.

After a brief account of some of the achievements of Soviet science, Mr. Crowther said that the spirit of the Soviet men of science rather than the impressive number and equipment of Soviet scientific institutions is the chief quality of Soviet science. Th atmosphere of youth is striking and the planning o the research and the relation of the work of th Institutes to industrial and political affairs are th subject of continuous organized discussion. One o the achievements of Soviet technology has been th provision of an immense body of good technica officers for the Red Army. The problem of socia relations between the scientific and the ordinar worker has largely been solved, and the scientifi worker has great prestige due to philosophical an practical reasons, and he is relatively well paid enjoying also special holiday facilities as well as th health and education services available to ever Soviet citizen.

TIMIRIAZEV CENTENARY CELEBRATIONS

On June 3, the hundredth anniversary of the birth of the Russian naturalist and plant physiologist Klimenty Timiriazev, was celebrated throughout th Soviet Union, special celebrations being held in Moscow.

Timiriazev was a member of an impoverished nobl family living in St. Petersburg. The interest which Darwinism excited in him while he was a studen persisted throughout his life. In 1864 he published three articles about Charles Darwin and his teachings In 1870 he was elected to the chair of botany at St Petersburg Agricultural Academy and in 1877 he became, in addition, professor in the University o Moscow, where he lectured on the anatomy and physiology of plants. He was the author of many scientific works which have now been issued as a twelve-volume complete edition. Timiriazev devoted fifty years of scientific activity to the study o photosynthesis. His work was marked by exactitude perfection being his constant aim, and his improvements in technique won the admiration of many scientific men.

The main problem of Timiriazev's scientific work was the occurrence of photosynthesis in relation to regions of the solar spectrum—a problem furthe worked on by A. Richter, V. Lubimenko, and A Danilov. Timiriazev established the fact that disintegration of carbon dioxide proceeds most intensively under the influence of red light. Proceeding from the principle that accumulation of dry plan matter reaches its maximum in the blue regions o the spectrum, Danilov has extended Timiriazev's work to show certain relationships in aquatic plants Timiriazev was also interested in the pigmentary apparatus of photosynthesis. He also investigated field ecology; and the urge that incited even hi most academic work was the practical aim of helping the farmer, and thereby the people at large.

Timiriazev lived to see only the first two year of the Soviet Revolution, of which he declared himself to be a warm supporter. He not only left severa brilliant students including Dmitri Prianishnikov Sergei Kostichev, and his son Prof. Arkady Timiriazev but also acquired a remarkable reputation throughou Russia as a popularizer of science. Maxim Gorky asked how it was that in some snowy hamlet of th Kherson province, or so far away as Perm, Timiriazev was known, and his books frequently asked for Timiriazev's support of the Darwinian theory has ensured popularity for it in Russia.

These facts have emerged from accounts of the ntenary sent to us by Profs. Alexander Schneideran, Alexander Popov, Nikolai Williams, B. Shiskin, d others.

The Moscow centenary meetings included one held the Timiriazev Agricultural Academy (the oldest gricultural school in the Union) at which Alexander aramonov read a paper on "Timiriazev as the ounder of Russian Darwinists", and others spoke botanical problems. At a meeting in the Moscow cientists' Club, there were present members of the cademy of Sciences of the U.S.S.R., the Lenin cademy of Agricultural Sciences, University of oscow, and others. The Vice-President of the cademy of Sciences, Leon Orbeli, said in an introuctory speech that whole generations had been and ere being trained on the basis of Timiriazev's assic work "The Life of Plants". The eighty-yeard Victor Krasilnikov followed with a portrait of miriazev as a "Knight of Science". Krasilnikov d not simply relate, but re-lived the past, and entioned that one of Timiriazev's aims had een the creation of hundreds of experimental elds in every province. Timiriazev's activity d not find much practical support in pre-revoluonary times, but Trofim Lysenko pointed out hat much of the present Russian drive for increased gricultural production could be ascribed to the pirit of Timiriazev. At this meeting, congratulatory legrams were read from the Royal Society, the oyal Agricultural Society of England, and Rothmsted Experimental Station.

The Timiriazev Agricultural Academy is indeed laying a great part in Soviet agriculture. President alinin, chairman of the Presidium of the Supreme oviet, has expressed the desire that the influence of he Agricultural Academy should be extended to llective farms throughout the country and should nbrace all cultivation. Important steps in such xtension work have already been made in many istricts in European and Asiatic Russia.

In 1903 Timiriazev gave the Croonian Lecture, nd eight years later was elected foreign member, f the Royal Society. He was also doctor *honoris ausa* of the Universities of Cambridge, Glasgow and eneva, and was a member of the Edinburgh and anchester Botanical Societies. These foreign memberships were and are a source of much pride the Russian people, and Timiriazev's statue in he centre of Moscow shows him robed in a Cambridge own.

CARNEGIE INSTITUTION OF WASHINGTON

YEAR BOOK No. 41 of the Carnegie Institution of Washington covers the year July 1, 1941–une 30, 1942, and in addition to the reports of he executive committee, the auditors and the resident, includes the reports of the departmental ctivities and co-operative studies. In regard to ar activities, the president states that the policy the Institution, in carrying on war research for he Government, has been to contribute the use its facilities, the services of its regular scientific aff and its regular overhead costs of providing dministrative services and the like. The Institution reimbursed for all additional out-of-pocket xpenses directly attributable to the research for overnment. In addition, it has loaned the services of some of its scientific personnel while retaining them on the pay-roll. In regard to finance, the favourable financial situation of the Institution which existed for three decades no longer persists, and for the first time in the history of the Institution the budget involves even a small predicted deficit. There is still some room for retrenchment, and a deficit appears for one reason because the annual grant from the Carnegie Corporation of New York is carried in a separate account since it is of a terminating nature. The downward trend of income from 1,695,900 dollars in 1936 to an estimated income of 1,175,000 dollars for 1943 if continued will, however, soon involve retrenchment of the regular operation of the departments.

Among the results of many investigations undertaken at the Mount Wilson Observatory, special reference is made to the increase in our knowledge of solar prominences, solar rotation and the general magnetic field of the sun through the application of powerful interference methods; to the analysis of the gaseous clouds of interstellar space and to the probable solution of the long-standing problem of the direction of rotation of the extragalactic spiral nebulæ. Activities of the Geophysical Laboratory and the Department of Terrestrial Magnetism have been directed so exclusively to war research that there is little to report. Priorities have, however, now been obtained for the materials necessary to complete the cyclotron at the Department of Terrestrial Magnetism, which is expected to be available for use during the coming winter. In the field of terrestrial sciences a number of reports of work on cosmic ray research at the Universities of Chicago and New York, the California Institute of Technology and elsewhere are included.

In the Division of Plant Biology further work has been carried out on the variables of the photosynthetic processes, structural elements in the higher plants and differences and relations in climatic races of flowering plants. Several projects have been completed on the influence of a desert environment on plant-growth, and it has been discovered that diatoms and related plants contain chlorophylls which are different from those of land plants. The Department of Embryology has continued its work along previous lines, and knowledge of the development of the human embryo has been pushed back about one week to the eighth day of gestation. Effective co-operation has been continued between the Department of Genetics and the Long Island Biological Association at Cold Spring Harbor. Detailed studies at the Department of Genetics of genetic effects caused by X-rays, ultra-violet rays and neutrons show consistent differences between the action of these radiations. Compared with gene mutations, fewer chromosomal breaks are caused by ultra-violet radiation than by X-rays, whereas the neutrons show a higher rate of chromosomal breaks than X-rays. Nearly six years study of the role of hormones in the regulation of the maternal instinct in rats has been completed by Dr. Riddle and his associates, who have found that the pituitary gland hormones play an important part in the production of stimuli that result in unlearned maternal behaviour. The Department has also co-operated with the Bureau of Plant Industry and the U.S. Department of Agriculture on problems arising from the war emergency, and is experimenting with the rubber-producing Russian dandelion and with fibre-producing hemp.

The small staff of the Nutrition Laboratory has been engaged in important war research in co-operation with groups at the Harvard Medical School. Projects under the Division of Historical Research have been of interest in supplementing the Government's programme of inter-American cultural relations. The knowledge possessed by the staff members of this Division with regard to geographical and economic conditions in Central America is also proving of assistance in connexion with the Government's war programme.

ACID NEUTRALIZATION IN INSULATING PAPERS

In the manufacture of paper-insulated condensers, impregnating materials are used to eliminate air pockets and to increase the dielectric capacity of the paper. With long use, particularly at high temperatures and under high voltages, traces of hydrochloric acid are liberated from chlorinated impregnants. The acid, and the salts formed by its reaction with the metal electrodes, ultimately decompose the paper and break down the condenser. This destruction is delayed by calcium, magnesium and other metals combined chemically with the paper which neutralize the hydrochloric acid.

An article by D. A. McLean (*Bell Lab. Rec.*, 21, No. 6; Feb. 1943) gives some of the results of an investigation carried out on the properties of Kraft and linen papers. Exchange reactions in cellulose materials do not take place in the principal constituent but in other organic materials with which cellulose is always associated, including lignin, pectic substances and pentosans. Differences in content of these minor components explain why papers differ so greatly in exchange capacity. Kraft paper, which is much superior to linen for condenser insulation, has several times the exchange capacity of linen tissue. In apparatus with which accelerated life-tests of condenser papers are carried out, condensers are heated in an oil bath and a continuous record made of the leakage current until the paper under test breaks down.

When aluminium electrodes are used in condensers made with paper impregnated with chlorinated compounds, decomposition of the dielectric proceeds from central nuclei about which the paper becomes partially carbonized. If the sample is dismantled after accelerated tests at high temperature and with D.C. voltage, these areas can be seen as brown spots. Under ordinary artificial light a photograph shows dark spots on a light background, but with ultra-violet light the spots fluoresce brightly.

Papers of high exchange capacity are capable of suppressing the formation of decomposed areas, and in two samples taken from a condenser after approximately equal periods of test at the same voltage, linen paper is shown to become thickly populated with decomposed areas which have grown from minute centres seen scattered through the sample, whereas Kraft paper shows only slight evidence of decomposition. More severe conditions of test are required to produce serious deterioration in the Kraft paper.

Superiority of Kraft paper as a dielectric is illustrated by comparing the energy losses at elevated temperatures in condensers made with this material and with linen. The lower power factor in Kraft paper is due to the binding of ionic material by its base exchange properties, which decreases the A losses. Values given in the article were determin at low potential gradients, under which conditio ionization is most readily detected by A.C. measu ments. Condenser papers of high exchange capaci reduce leakage current; and typical results obtain with linen paper under accelerated test conditio show a rapid increase of leakage and dielectric failu after 40 hours. In contrast, Kraft paper has a mu more stable leakage current and a life of 350 hou as its high base exchange capacity suppresses deco position. These studies of exchange reactions condenser papers impregnated with chlorinat compounds have led to the development of stabilize which extend the life of condensers, under stat severe test conditions, to several thousand hours.

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Head of the Electrical Engineering Department—T Registrar, Technical College, Sunderland (August 6).

Lecturer (man or woman) in Chemistry in the Croydon Po technic—The Education Officer, Education Office, Katharine Stre Croydon (August 6).

Speech Therapist (full-time)—The Secretary for Educati Education Offices, York (August 6).

Graduate Assistant Master to teach Engineering Drawing the Middlesbrough Technical School for Boys—The Director Education, Education Offices, Middlesbrough (August 7).

Teacher of Mining Subjects in the Denbighshire Techni College, Wrexham—The Director of Education, Education Offic Ruthin (August 7).

Assistant Master (preferably a Graduate with works experien to teach Technical Drawing and Mathematics in the Sunderla Junior Technical School—The Director of Education, Educat Offices, Carlton House, Mowbray Road, Sunderland (August 9).

Assistant to teach Mathematics and other Junior Engineer Subjects—The Principal, County Technical College and School Art, Newark, Notts. (August 9).

Lecturer in Mathematics in the Constantine Technical Colle Middlesbrough—The Director of Education, Education Offic Middlesbrough (August 14).

Head of the Department of Child Development in successi to Dr. Susan Isaacs—The Secretary, University of London Instit of Education, at University College, Nottingham (August 14).

Lecturer (temporary) in Physics—The Acting Secretary University Court, The University, Glasgow (August 15).

Assistant Lecturer and Demonstrator in the Physiolo Department—The Secretary, The University, Birmingham (Aug 18).

Lecturer (temporary) in Chemistry—The Registrar, Univers College, Southampton (August 25).

Professor of Physiology, a Senior Lecturer in Anatomy, a a Senior Lecturer in Physiology, in the University of Ota Dunedin—The High Commissioner for New Zealand, 415 Stra London, W.C.2 (August 31).

Chemist and Assayer on the establishment of the South Afric Mint, Pretoria—The Secretary, Office of the High Commissioner the Union of South Africa, South Africa House, Trafalgar Squa London, W.C.2 (August 31).

Heads of the Departments of Physiology, Medicine, a Surgery—The Bursar, Royal Veterinary College and Hospital, The University, Reading (October 1).

Chair of Naval Architecture—The Acting Secretary of Univ sity Court, The University, Glasgow (October 4).

Engineering Workshop Instructor for service in the Bu Junior Technical School and Bury Municipal Technical College (Ev ing Classes)—The Director of Education, Education Offices, Bury

RESEARCH AND PLANNING

THE planning of research in Great Britain and the efficient utilization of the scientific resources of the country have come increasingly to the forefront in recent months. The contribution of science to the war effort was the subject of comment by the Minister of Production in recent speeches, and Government provision for research was discussed in the House of Lords on July 15 and 20 (see NATURE, July 31, p. 129). On June 1, Sir Stafford Cripps made an important statement to the Parliamentary and Scientific Committee on "Future Requirements of Research and Technical Development in Great Britain and Supply of the Necessary Personnel", and that Committee has submitted a memorandum on scientific staffs to the Departmental Committee on the Training of Civil Servants. The Parliamentary and Scientific Committee has also prepared an important report on Coal Utilization Research and the National Economy, and a deputation from the Committee on this question was received by the Lord President of the Council on June 29. A research sub-committee of the Committee on Post-War Planning of the Institution of Electrical Engineers has issued a report on the organization of post-war electrical research, in which the formation of a British Electrical Research Board is proposed as an instrument to secure the maximum progress in the application of scientific research within the electrical industry in Great Britain.

Behind the details of any such concrete proposals there are broader issues which were touched upon, for example, in Sir Robert Watson-Watt's presidential address to the council of the Association of Scientific Workers in May, and in a letter from the chairman of the Joint Council of Professional Scientists and the presidents of the Royal Institute of Chemistry and of the Institute of Physics which has appeared in *The Times* and elsewhere. Sir Robert Watson-Watt pointed out that those who believe that a political scientist is a menace to science overlook the fundamental character of science. The fact that scientific workers are also citizens with responsibilities as members of the State which transcend their individual needs and interests means that they are bound to attempt to exert some influence on the public policy of the State. As scientific workers they are concerned with the accumulation and acceptance of ordered knowledge, but as citizens they are profoundly concerned with the application of this accepted knowledge for the general good of the State and of the world at large.

That position is not inconsistent with the warning which is sounded in the letter from the Joint Council of Professional Scientists mentioned above, and repeated in a subsequent interview by Sir Robert Pickard, against exaggerated expectations of rapid results. The time-lag in the application of research is one reason why it is important that immediate preparation should be made for reconstruction, and the necessity for planning a long way ahead is one of the reasons why planning is as important for the advance of science as of society. There is, in fact, as Sir Robert Watson-Watt remarked, no alternative to planning but the dream-world which he labelled "planned sporadicism".

The real question is the character, the objectives and the limits of planning. It should be a means to an end and not an end in itself; and the purpose or end which planning is to serve is the all-important criterion as to whether planning is good or bad. On this we may well note the denial in the letter from the Joint Council of Professional Scientists of the contention that the man of science is pre-eminently fitted for the position of leader in a democratic community. The weakness of that position, which is rarely claimed by responsible men of science, has been shown admirably by Prof. E. H. Barker. The man of science might well be consulted more frequently than he has been in the past, and we may well develop a more effective technique for utilizing his advice and services. When that advice has been given, however, the duty of the man of science, as such, is at an end; his claims to be considered an administrator or statesman must depend on his possession of knowledge and ability covering wider fields. The argument that scientific knowledge and ability are not inconsistent with the possession of administrative ability, and that they should not be allowed to debar the scientific worker as such from high administrative positions, must not be construed into an argument for the placing of scientific men or women in administrative positions on the ground of their scientific qualifications. That might, indeed, be a short cut to a soulless technocracy indistinguishable from despotism.

Fortunately, there is no reason to rate that danger as high. The emphasis laid in recent pronouncements on the education of scientific workers on the importance of a sound general education as a basis for specialization, like the emphasis now being laid on the necessity for any administrator to possess a broad appreciation of the nature of scientific method, the achievements and potentialities of research and of the structure and methods of scientific industry, is some assurance that mistakes of the past are on their way to being rectified. Effective planning, in science as elsewhere, presupposes a high standard of education in the broad as well as in the technical sense. No plans for post-war reconstruction are, in fact, more important than those which relate to education, whether of the administrator or of those whom he is to serve, and the success or failure of our efforts to build a better world and to achieve the four freedoms, like the security of our democratic institutions, ultimately depend on our ability to meet the searching demands which they make on us in character and in intelligence.

Remembering, therefore, that planning in science, as in a democracy, must be planning for freedom, and limited to those measures which will further the broad objectives desired by the community, we can proceed to consider the measures which may be required in particular fields. It is natural that our closer association with the U.S.S.R. should stimulate interest in Soviet achievements, which Mr. J. G. Crowther recently dealt with in the Trueman Wood lecture before the Royal Society of Arts, and on which Sir Stafford Cripp touched in his statement before the Parliamentar and Scientific Committee. Those achievements ar often compared with the research effort of Grea Britain, much to the disadvantage of the latter, an it may well be that Sir Stafford Cripps is right i holding that we have even yet not realized to the fu the place that research should take in developmen and production.

Admitting that the pre-war provision for researc in Great Britain compares unfavourably with tha of the United States or of Soviet Russia, it must no be supposed that the position can be rectified immediately by the allocation of financial and materia resources more commensurate with the effort required The supply of personnel alone, as Sir Stafford Cripp observed, is an obstacle to rapid expansion, and th difficulties in obtaining a sufficient number of researc workers at present experienced by the various Suppl Ministries are likely to be encountered in industr and elsewhere after the War. A shortage of thi kind can only be eliminated as a result of an appropriate educational policy. The research worker moreover, is only one member of the team of scientifi workers and technicians required; the skille technical personnel for the technical applications o scientific research and for the engineering an development work involved must also be available.

To increase the relatively small output of suitabl men and women from the universities and highe technical colleges is a matter of educational policy, and this is ultimately the responsibility of the State, which now provides directly or indirectly a very large measure of the finance and planning of educational facilities. As yet it has not been decided how we are to plan and manage the whole range of basic and applied research necessary to safeguard the future of our industries. What is required, Sir Stafford said, is to increase the volume of research, both basic and applied, and, at the same time, to introduce some measure of planning so as to make the best use of the available resources. We must also decide through what agencies we want this research to be carried out, and how much of our national wealth we are prepared to devote to the research itself, as well as to the provision of the personnel for research, technical development and production engineering.

Sir Stafford Cripps is clearly of the opinion that the need cannot be met entirely by private research institutions—they have not the resources available in national institutions—but he did not commit himself so far as the report of the Committee of the Institution of Electrical Engineers in condemning the competitive basis of industry as opposed to the re-organization of research on co-operative lines. The proposals for a British Electrical Research Board may be held to depend too much on a basic change in the character or structure of industry, the value of which is at least open to debate.

Sir Stafford Cripps himself looks rather to the establishment of further State institutions—he instanced the need for a first-class institution for aeronautical research—as the feature of a State research service. He also considers that we need a State scientific service, apart from, but on a parallel with, the administrative Civil Service. Such a service should be under the control of a single responsible Minister able to draw together all the threads of scientific effort so far as the State is concerned. The actual administration of the research should be under the control of a body of men of science : he suggested that the Royal Society, if provided with a special administrative staff for the purpose, might perform that function.

While he emphasized that these matters are primarily for scientific workers to determine, even if their decisions must take the form of advice, Sir Stafford regards such developments as a natural growth out of the present haphazard system. He suggested the introduction of a consolidating and enabling Bill to deal with the whole question, and to correlate it with the work of the universities and the industrial research institutions. He believes we must envisage spending after the War at least ten times as much as in 1938–39 if we are to make headway or even to keep abreast in such industries as the light chemical, optics, radio, civil aviation, as well as in the heavier industries.

In replying to a question from Prof. A. V. Hill regarding the means of raising the status of the scientific worker, the importance of which Sir Stafford Cripps had stressed, Sir Stafford suggested that this would be one consequence of establishing a Government scientific service and that the process would be further assisted by the expansion of our research effort. Prof. Hill also raised the question of the possibility of a superannuation scheme not only in universities and in some Government establishments, but also throughout the scientific services and industry. Sir Stafford Cripps agreed that some correlation in this field would be possible, but valuable as such a scheme would be as a stimulus to the interchange of personnel, it involves certain dangers to the individual initiative and independence of the scientific worker. The dangers of State control are elaborated by Prof. M. Polanyi in a recent paper on "The Autonomy of Science" (*Mem. Proc. Manchester Lit. and Phil. Soc.*, **85**, 19–38). Prof. Polanyi's admirable argument for the importance of the autonomy of science, however, will be as warmly welcomed by those who are urging the more rational use of our scientific resources as by those who attempt to argue that planning and science are incompatible.

Prof. Polanyi himself appears to confuse the broad planning and orientation of scientific effort to secure a steady advance along the whole front and the apportionment of scientific effort where fresh knowledge appears to be most required, with the interference with scientific results and the suppression and distortion of truth which we have witnessed in the totalitarian States. Scientific men can never give a guarantee of results. They cannot fit their discoveries to suit preconceived ideas or desires without disloyalty to the quest for truth which is of the essence of their calling. A research worker who deliberately concealed some fact in the field of vaccines, for example, because it was inconvenient or inconsistent with a Government policy of vaccination, is indeed disloyal to science and could no longer claim to be a scientific worker. He would not, however, be impairing that loyalty and his professional integrity if, as Prof. Polanyi appears to argue, in response to a request from the leaders of his profession, he laid aside for the time those investigations to undertake work in some other field, for which he was equally qualified, where a solution to some other problem was urgently required for the relief of suffering.

It is no argument against the planning of science that we cannot tell where the fundamental discoveries or the real advances will be made. That view has indeed been strongly challenged by Bavink, who argues that in the physical sciences it is possible to state within limits exactly where lie the problems still to be solved, though he does not claim that the applications of such fundamental discoveries are equally predictable. What is axiomatic is that we cannot escape the responsibility for prosecuting scientific effort, where according to our best judgment it is likely to be most fruitful. That judgment may prove to be mistaken, but if it is honestly made, based on a critical survey of the facts of the whole situation so far as they can be determined, we are at least not open to the charge of prostituting science or wasting scientific resources. We have made an attempt at something more than a guess at the direction of further progress, and the mistake itself can prove a stepping-stone for a further advance.

Scientific workers should not therefore be reproached for disloyalty to science when they accept a broad direction as to the fields in which they should work. Planning to that extent does not encroach on the essential freedom of the scientific worker, his creative powers and initiative, his professional integrity. Prof. Polanyi has described this position of the scientific worker and the indispensable autonomy of his creative life so admirably that it is, to say the least, unfortunate that he should impute to the type of planning and organization of scientific effort and resources urged by Sir Stafford Cripps an attempt to interfere with the internal discipline of science and the decisions leading to discovery. Sir Stafford Cripps, like every other serious advocate of the more effective organization of our scientific resources, makes it clear that while the community may, and should, claim the right to determine within broad limits the extent of the resources to be devoted to scientific and technical research, and the broad allocation of those resources between different fields and on major projects, that allocation must be subject to the advice of men of science themselves, and the technique and the manner in which the particular problems are attacked must be the affair of the scientific worker alone.

Planning for freedom in this manner accordingly involves a more efficient organization of the scientific community itself, the elaboration not merely of the machinery for exercising more effectively scientific discipline, particularly in those borderlands of the sciences where advance has so often been most fruitful, but also of the machinery for assisting the allocation of effort between the different fields and determining the major programmes of work. Moreover, there must be the proper organization of the scientific community in its relations with the society and nation of which it forms a part, so that scientific advice can be more effectively brought to bear on the problems of the nation and supplied in terms understood by administrators and the people at large. These considerations are all involved in the effective planning of science for freedom. The education of the man of science himself is only a part of the large task of education to be undertaken, and in addressing themselves to those problems of the more effective organization of our scientific resources on which Sir Stafford Cripps touched and the rapid expansion of our endowment of research, scientific workers must not overlook these important questions of the re-organization of their own community, so that their knowledge may be presented to the community and its leaders in the most effective channels and in the most lucid and widely understood manner.

SOURCES AND IDENTIFICATION OF TIMBERS

Timbers of the New World

By Samuel J. Record and Robert W. Hess. Pp. xv+640+58 plates+8 maps. (New Haven: Yale University Press, 1943.) 10.00 dollars.

THIS monumental work is packed with most valuable and up-to-date information. In Prof. Record's well-known scientific and methodical manner no stone has been left unturned, and no effort spared, to treat the vast subject with accuracy. Probably in no part of the world could one find authors so well equipped, at least as regards the timber, to handle this great task, for apart from their own wide knowledge, they have access to the unique collection of 40,600 wood samples at Yale University, which is probably the largest collection of wood specimens in the world. Moreover, for the past eighteen years Record has published a journal known as *Tropical Woods*, which has included information on this subject gathered from all quarters of the globe. In addition, the long list of well-known names under the heading of "Bibliography" displays an exhaustive range of research.

The book is the more welcome since it arrives at a moment when we are unexpectedly faced with an alarming depletion of our own reserves of forest, and many sources of supply have been cut off, some perhaps permanently, and others at least for a long period. Although "The New World", as the authors term it, has already provided a large and regular supply of timber for many years, it may very well be that it still contains a great remaining store—at least of hardwoods—in a world the history of which reveals one continual source of forest destruction—by war, by fire, and by the march of civilization—which in all ages has destroyed without replenishing a most necessary element for its prosperity.

The book contains detailed descriptions of each tree, its geographical situation, its timber and comparative durability, the purpose for which it can be used, and last but not least the multiplicity of names by which it is known in all the different countries. This multiplicity and duplication of names, in the Brazilian timbers alone, has caused complete confusion, one which might justly be compared with th difficulty which confronts the chameleon when place upon a Scottish tartan. Many of the common name are repeated for woods which are of entirely differen qualities, and indeed of different colour, but a named alike. Record's work will help to correct thes difficulties.

Mr. J. S. Gamble's brother—Colonel Gamble, wh spent a great number of years in Brazil—got togethe an exhaustive and well-chosen selection of the timber of that country, which collection came into m possession more than twenty years ago, and afforde a very useful basis for checking up those specimen which I already had, and introducing new kind not formerly available. The whole collection wa named according to the local names of the distric from which the specimens had been taken, and o this account the greatest difficulty in identificatio was experienced.

When it is realized that 1,100 genera are include in the book under notice, a faint impression of th Herculean effort can be obtained.

Those who are interested in the timbers from Sout America will have their task made easier, although the will still meet with some unexpected changes of name

It is not often that a first-class botanist has th opportunity of also becoming an experienced timbe expert. In this case, however, Record is a past master as botanist, forester, and in the intricat study of wood structure.

The association of the botanical relationship o trees and the wood which they produce is, of course extremely close, and the dual study is of the greates interest, but whether in a treatise on *timber*, or th *trees* which produce the timber, the subject shoul be carried into the realm of families of trees, migh be open to question. From the commercial, or craftsman's point of view, the family of the tree which ha produced the wood is of no importance; for example beech belongs to the family Quercineæ, which includes also the oaks and chestnuts, and Castanopsis the woods of which are entirely different. Again, t couple the botanical name with the common nam of the wood only adds confusion.

Of late in Great Britain the required conditions o some contracts have had added to the common nam of the timber the botanical name, as for exampl English ash, *Fraxinus excelsior*, whereas the tern "English" ash is fully sufficient. Many hones operators will not sign the conditions of such contracts, as they contend that they do not know th botanical side, but the qualification 'English' alon would be sufficient to ensure a correct delivery. In a demand for teak the additional name is superfluous, the name Burma or Indian teak being sufficient, as there is only one species available. Again th botanical term is unnecessary, but when we come t supplies of mahogany the case is different. Th authors state "*Swietenia* [is] the source of the onl and true mahogany", which pronouncement may b correct, but also may not. A very controversial subject is opened if it is proposed in any individua endeavour to confine the supplies of mahogany t Swietenia sp. For more than three hundred year mahogany-like woods have been passed as mahogany and the resulting confusion, while it has had littl notice throughout the United Kingdom, has caused much dispute and litigation in the United States The subject is one on which a great deal might be said, but it is sufficient for the present review t direct attention only to the difficulties which are encountered if botanical terms and families of trees are to become an integral question in relation to timber.

These remarks, in any event, although suggested by the book, do not in any sense affect its usefulness, as the method adopted enables the reader to make easy reference. The whole work is supplemented by an excellent index, covering no fewer than fifty-two pages—by itself a remarkable achievement, which must have required great diligence and patience.

There are thirty-six well-chosen illustrations, of unusual interest, and twenty-two pages of photomicrographs, as well as exhaustive "Lists of families classified with reference to special properties and uses of their bark, leaves and timber".

In addition, the book contains illustrated maps, whereon are noted the areas whence the various woods are obtainable, with particular reference to those to which individual species are limited; information, both for the present and the future, of inestimable value.

This book, without which no arboricultural library would be complete, embraces all the interests of forestry and timber, and provides a fund of information never before available, surpassing those valuable contributions on this subject which we already possessed, and even the work which Prcf. Record himself and his associates have formerly completed.

ALEXANDER L. HOWARD.

PLACE-NAMES OF CAMBRIDGESHIRE

The Place-Names of Cambridgeshire and the Isle of Ely

By P. H. Reaney. (English Place-Name Society, Vol. 19.) Pp. lxi+396. (Cambridge: At the University Press, 1943.) 23*s*. 6*d*. net.

A LOT of water has flowed even under the bridges of the Cam since Prof. Skeat published his monumental work on the place-names of Cambridgeshire, and much new information, archæological and otherwise, has accumulated since that date. It has been shown that the area was peopled by Anglo-Saxon folk from a very early date—before the end of the fifth century—and the researches of such investigators as Sir Cyril Fox, T. C. Lethbridge and others have thrown a flood of light on these early migrants, their origins, movements and modes of life. The place-names of the county, in spite of the absence of *ingo's* endings, confirm the existence of these early settlements. The occurrence of personal names, ancient and rare words and primitive forms of compound make this clear. Celtic influence, on the contrary, seems to have been slight, so far as the place-names are concerned, though the river-name *Grante* and some other stream names do appear in some compounds. Scandinavian influence, though not strong, is noticeable, though only two villages—Toft and Bourn—are of pure Scandinavian origin. Again, Anglo-Norman influence was also apparently not strong.

The author will scarcely expect his work to be used as armchair reading; yet the fact is that anyone who knows the county finds himself looking up the name of village after village for the interest of what he will learn. It is dreadful to find by how narrow a margin Grantchester—which should be spelt Granteseta, meaning the settlers on the Granta—escaped being Grandchester, a horrid hybrid meaning the big Roman camp! Westley Waterless actually means water clearings to the west (of Dullingham); waterless being a corruption of waterlees or water meadows.

After an all too short introduction and some necessary fore pages, an account is given of the river-names, followed by those of the famous dykes. There then comes an account of Cambridge and its immediate environs, including the origin of the names of many of the streets. The rest of the book is devoted to the villages of the county arranged by hundreds, brief mention being given in each case of some names in the parish of fields, woods, houses, etc., which are of interest from an etymological point of view. These references, in the nature of the case, cannot be complete; space would not permit, and many people with local knowledge will necessarily look in vain for the origin of some familiar but not understood field-name. An index and three maps in a folder complete the volume.

This is certainly a work to possess, and the author is to be congratulated on its production. A small point struck me as interesting. How many inhabitants of the south-west part of the county remember that the villages of Great and Little Chishall and Heydon were transferred to Cambridgeshire from Essex so late as 1895? I can only testify that to-day the emotions of Heydon are strongly Cambridgeshire-wards, with indeed some slight antipathy to Elmdon, the nearest place in their former county of Essex!

M. C. BURKITT.

X-RAYS IN INDUSTRY

X-Rays in Research and Industry

By Dr. H. Hirst. Pp. 96. (Melbourne: Tait Publishing Co. Pty., Ltd., 1942.) Cloth, 7*s*. 6*d*.; paper, 5*s*.

IT seems to be the fate of the physicist to provide the tools for others to finish off the job. X-ray physics has provided a very practical tool for studying the inner structure of materials. Inevitably it has become the concern of the chemist, metallurgist and engineer. This, however, is a good omen, and for further effective application of X-ray work one looks forward to increasing contributions from people interested in the structure of materials from points of view other than that of the pure physicist. This book by Dr. Hirst, who surveys the field for the metallurgist, is a welcome sign.

Dr. Hirst considers both X-ray diffraction and X-ray radiography, and sets himself two tasks: to point out the type of application in which the X-rays might profitably be employed; and to give such guidance in technique that the metallurgist might hope to tackle the X-ray work himself. He has achieved both aims admirably, and made a useful contribution to a literature which has not catered greatly for the practical worker. His presentation is brief, but to the point.

In X-ray diffraction, the author has chosen the applications to study of alloy systems and stages in precipitation, chemical testing, temperature effects, grain size, and the structural changes accompanying plastic deformation. These applications are well known and have been described before, but scarcely with such emphasis on practical procedures. This makes the book useful to the newcomer, who is given tangible directions to go on, and interesting to the older hand who can compare notes and occasionally criticize. One criticism which might be allowed is that the working metallurgist will not wish to be limited to a circular camera technique which involves the reduction of his specimens to the form of filings or powders. He would soon require an arrangement to take normal whole specimens, preferably permitting of metallographic as well as X-ray examination. One also misses reference to the X-ray methods for measuring internal strains, which are finding extensive application, for example, in the examination of welds and problems of stress relief. In his treatment of radiography, Dr. Hirst has again emphasized the practical side. Industrial radiography has grown rapidly since the War began, and now consumes photographic film at a rate which would surprise the cinema industry. The standard is not uniformly high, and the practical points made by the author are not out of place. A clean radiograph, especially of an awkwardly shaped component in heavy metal, is often simpler in theory than in practice, and in this connexion, perhaps more reference would have been made to the use of filters in the primary beam, and to devices other than the use of lead paste to ensure the vital screening from unwanted radiation.

Whether the treatment of the principles and practice of X-ray diffraction is sufficiently comprehensive, as Dr. Hirst suggests, will depend on the work with which the practitioner is likely to be most concerned. In many fields it will certainly suffice for anyone to make a confident beginning, in which he will be aided by the initiative of certain manufacturers in putting reliable X-ray equipment on the market. Experience has shown that various types of work can be reduced almost to routine and undertaken by personnel without highly specialized training. On the other hand, there will always be investigations calling for considerable experience and versatility in interpreting and adapting the X-ray work. There will also be firms who may wish to use the method occasionally but not so often as to justify the expenditure on equipment and staff. Then there is a real case for the work to be undertaken by a central organization. To some extent this has been met in Great Britain by the facilities provided by the Department of Scientific and Industrial Research and by university laboratories. But the problem would repay systematic study, for the issues involved are not peculiar to X-ray work, and are likely to be encountered more frequently with the increasing complexity of scientific development and the growth of specialized techniques.

W. A. WOOD.

MAP PROJECTION

An Introduction to the Study of Map Projection

By Dr. James Mainwaring. Pp. viii+114. (London: Macmillan and Co., Ltd., 1942.) 5*s*.

IT is a common complaint that examination syllabuses exert an undue influence on the school curriculum; but it is a chastening reflexion that, in the case of map projections, the regulations of examinations boards have, to a considerable extent, saved a valuable subject from unmerited oblivion, though not from neglect. One of the worst reasons for the study of a subject in schools is that "questions are set on it", because it produces an attitude which leads to cramming.

The fact is that we have not hitherto evaluated the subject as an educational instrument, and there is now a danger that utility in the limited sense may receive too great prominence; those who feel most strongly would stress rather its educational value.

What we teach in the subject will be conditioned by our reasons for teaching it; the kind of textbook required will emerge from these decisions. It is clear that books written to meet the needs of the cartographer are only suitable in schools for purposes of reference. The school should aim at giving a sound grasp of principles to as many pupils as possible and, in any event, as those specializing in geography may be on the arts side, we must regard the basic mathematical equipment as of school certificate standard only.

Dr. Mainwaring has made a noteworthy contribution to the teaching of the subject: his book, ostensibly written as an introduction to map projections, aims at Higher School Certificate standard; actually he presents to us a well-considered scheme admirable in plan and execution, likely to develop interest and to provide a suitable foundation for more advanced work.

He writes under headings: (*a*) the problem; (*b* the process; (*c*) the application. The first deals with the relevant properties of the sphere, explains such terms as great circle, loxodrome and orthomorphic, and leads up to the aim of map projections. The explanations are accompanied by effective diagrams, the most striking showing great circle and west to east routes from Madrid to Peiping on Mercator and gnomonic nets; the section ends with six different nets between longitudes 0° and 15°.

Describing processes, projections are classified and dealt with as cylindrical, conical, zenithal, modified and arbitrary. Again the method is comparative and in each case a formula is obtained. In this connexion, it may be noted that the equation for the position of Molleweide parallels is proved but does not provide a ready means of solving the problem; may I suggest that a graphical solution has educational advantages over the use of the table? In the case of Mercator, it is suggested that the distance of a parallel represented by $R\int\sec\theta d\theta$ may be found by performing the summation $\Sigma_1^n\sec(x-\frac{1}{2})^\circ$, where n is integral, using the 30′ column in four-figure tables of secants. Up to 80° this gives 139·56 equivalent equatorial longitude degrees, that is, 2·436 R.

The third section considers the choice of projection in relation to its use; it begins with a useful summary of the properties of those studied and is illustrated by well-chosen diagrams. The world is shown on four maps the uses of which are critically examined; two other world maps illustrate the advantage of interrupted projection. Africa and South America are exhibited on four nets with the same equatorial scale. North America is used to compare Bonne's and Lambert's, while the U.S.S.R. illustrates the use of two standard parallels.

It is to be hoped that those who adopt the book will spread the work over the two-year geography course; the contents will be best absorbed gradually, if their full implications are to be appreciated. Perhaps also the mathematical staff would like to make use of the book.

As a final note, there are still worlds to conquer in the field of useful projections; to encourage such research we cannot have too many interested students.

The author is to be congratulated on producing a book so uniformly good in text, diagrams and questions; the publishers, too, have done justice to it.

A. HINCKLEY.

An Atlas of Stellar Spectra

With an Outline of Spectral Classification. By W. W. Morgan, Philip C. Keenan and Edith Kellman. (Astrophysical Monographs, sponsored by the *Astrophysical Journal.*) Pp. vi+36+55 plates. (Chicago: University of Chicago Press; London: Cambridge University Press, 1943.) Price 60*s.* net.

THIS much-needed atlas defines a two-dimensional classification system of stellar spectra by means of a sequence of standard spectra, many of which are illustrated in the fifty-five photographic prints forming the main body of the work. The spectra were taken specially for the purpose on a small one-prism spectrograph attached to the 40-in. Yerkes refractor. The standard stars chosen, which are mostly brighter than the eighth apparent magnitude, are of types from *O*5 to *M*2, and were selected to exhibit a large range of luminosities. A given spectrum is considered uniquely classified when its spectral type (one of the conventional seven classes subdivided decimally) and its luminosity (one of five classes ranging from supergiants to the main sequence) are specified.

The "Outline" accompanying the prints gives a brief review of the taxonomic principles involved, and goes on to describe the criteria employed for both co-ordinates of the classification, and to tabulate the standard stars. No originality is claimed either for the system defined or for the criteria used: of necessity they are both evolved from work done, mainly at Harvard and Mount Wilson, by many previous investigators. The spectral types are closely correlated with colour, and will thus be invaluable in studies of interstellar absorption. The luminosities, when calibrated, will make possible the determination of accurate spectroscopic parallaxes on low-dispersion spectrograms.

The prints themselves are excellently reproduced and show well the lines, often quite faint, which are used for the classification of spectral type or luminosity. They are negative prints and can thus be compared directly with spectrograms in the observatory. The descriptions, though concise and lucid, are reproduced in a manual script which does not enhance the appearance of the Atlas, but the "Outline" is printed in the impeccable tradition of the "Astrophysical Moncgraphs". It is not too much to predict that this work will quickly become a tool indispensable to every practical astrophysicist.

The Earth and Man

A Human Geography. By Prof. Darrell Haug Davis. Pp. xxiii+675. (New York: The Macmillan Company, 1942.) 21*s.* net.

AS geographers become more agreed on their province of study, they approach nearer to what might well be termed human ecology and find a field of observation that has been largely neglected in other studies. The analytical outlook, in geography as in other sciences that deal with living organisms, gives place to the more difficult synthetic outlook, which in geography is one of great complexity, because man is more concerned in improving, or at least in changing, his environment than in being dominated by it. In human ecology, the organism's reaction is far greater than in plant and animal ecology, and the risk of neglecting human influence on surroundings is a constant danger.

Prof. Davis has written a careful, though not profound, introduction to this aspect of geography, but he claims no further aim than the writing of a text-book for the early stages of university work, and this no doubt explains his general avoidance of problems in social geography. He has produced an admirable survey of the factors that decide the grouping and pattern of human distributions with special reference to North America. The rest of the world—especially the monsoon lands of Asia—are not neglected, but the book is primarily for American students. It is admirably illustrated with maps, diagrams and photographs, and has a full index. The bibliographical references might well be on a wider scale. R. N. R. B.

The Bushman Tribes of Southern Africa

By A. M. Duggan-Cronin; with an Introductory Article on the Bushman Tribes and Descriptive Notes on the Plates, by D. F. Bleek. Pp. v+15+40 plates. (Kimberley: Alexander McGregor Memorial Museum, 1942.)

ALTHOUGH the actual text of this book comprises only 14 pages, a great deal of reliable and interesting information is given on the physical characters and culture of the Bushman tribes. This information is supplemented by a useful map showing the distribution of the various tribal units. It would, perhaps, have been a useful addition to have provided a short key to the rather baffling system of phonetics employed in writing native words. Condensation was naturally necessary in so brief an introduction, but this brevity is in certain cases rather unsatisfactory. It is tantalizing to be told that: "In all tribes they make rain in some manner", but to be given no hint as to the procedure adopted in any tribe.

The story of these people is a sad one: "They are being gradually forced into servitude of black or white men, and absorbed into the coloured population of South Africa". The forty plates, most admirably reproduced from excellent photographs, constitute a permanent and valuable record of these doomed people. In them are preserved scenes from their daily life, records of many of their social and cultural activities and the physical characters of certain well-selected types. The National Research Board of South Africa and the authorities of the Alexander McGregor Memorial Museum are to be congratulated on the production of a publication of such perfection in the year 1942. F. WOOD JONES.

The Cathode Ray Oscillograph in Industry

By Dr. W. Wilson. Pp. xii+150+42 plates. (London: Chapman and Hall, Ltd., 1943.) 12*s.* 6*d.* net.

APPLICATIONS of the sealed-off cathode-ray tube to the field of radio have been previously well treated, so the author gains by concentrating on other applications, which are shown to be wide and valuable. Controlling electron beams in cathode-ray tubes, electron diffraction tubes, and electron microscopes exhibits many common features, and the author brings these and related topics up to date in book-form. He also shows that the sealed-off glass tubes and the metal continuously evacuated tubes have their separate fields of application and are not always competitors. He gives some of the latest electron microscope photographs, and shows how essential this new instrument is in many fields of research. It is unfortunate that the War has further retarded the development of electron microscopes in Great Britain, an opportunity which even private generosity has neglected. The text is well produced considering the present conditions, and includes the essential references. L. E. C. HUGHES.

ARTIFICIAL PRODUCTION OF DIAMONDS

By DR. C. H. DESCH, F.R.S.

THE claim of Moissan to have produced diamonds by the rapid quenching of molten iron or silver containing carbon in solution, causing solidification to take place in the interior of the mass under high pressure[1], was widely although not universally accepted, and found its way into the text-books. Le Chatelier, himself a very careful experimenter, was sceptical of the identification[2]. The later work by Sir Charles Parsons[3] tended to show that pressure alone was not responsible for the separation of carbon in the form of diamond, but that the entrapped gases played an essential part. In all these experiments the crystals obtained were very small, and were chiefly identified by their hardness, high refractive index, density and single refraction. It does not seem that Moissan's crystals were ever subjected to tests by any other worker, although Sir William Crookes[4] satisfied himself that small true diamonds had been produced. Moissan's own statements are categorical. Quantities of a few milligrams of black crystals prepared from silver and of transparent crystals from cast iron were burnt in oxygen, and after deducting the unburnt ash the weight of carbon dioxide obtained corresponded almost theoretically with the combustion of elemental carbon. The crystals had the correct density of 3·5.

Parsons used other methods. Besides repeating the experiments of earlier workers, with negative results, he produced instantaneous high pressures by means of explosives and by firing high-velocity rifle bullets into cavities containing the materials to be compressed. Experiments were also made in a 2,000-ton hydraulic press with electrical heating, producing only graphite. Some of the experiments with gases gave crystals which were apparently diamonds. On attempting to carry the process further, Parsons felt some doubts as to the identity of the crystals which he had formerly obtained, it being easy to mistake spinels (which are octahedral and optically isotropic, and in general appearance resemble diamonds, and are also highly resistant to the chemical agents used to dissolve mineral matter) for diamonds. It is true that on heating some of the crystals in a stream of oxygen flashes had been seen, indicating combustion, but it was found that in the long series of operations needed for the isolation of the crystals, particles of dust were liable to enter, and that it was these which were burning. Parsons, repeating his experiments with meticulous care, with the assistance of Mr. H. M. Duncan, found that his own crystals remained unburnt. The two investigators also repeated the experiments of Moissan and of others who had claimed to have produced diamonds, but again with negative results. Inquiries in France failed to locate any of Moissan's original crystals. Sir Charles Parsons, with the scrupulousness which was characteristic of him, submitted the whole of the evidence, including his own note-books and much correspondence with friends of Moissan, to the editor of NATURE, at whose suggestion the writer prepared a summary[5] leading to the conclusion that there was no satisfactory proof that diamonds had ever been obtained by any artificial process.

An earlier and less famous investigator who claimed to have produced artificial diamonds was James Bannatyne Hannay. In 1939, Prof. W. M. Travers[6] gave some account of the career of Hannay, a most ingenious and persevering experimenter, who as a boy was attracted by chemistry, and without any college training, becoming an assistant in the laboratory of a Glasgow chemical works, soon published a series of papers on improved analytical methods. Sir William Ramsay was a friend of his boyhood, and discussions between the two must have done much to stimulate Hannay's interest in research. He became works manager, but retired in 1876 on account of ill-health, and two years later became an assistant lecturer in Owens College, Manchester; actually he worked there only for two months, the reason being again bad health. He then took up private technical work, presumably as a consultant, and to this later period belong his most important investigations. He was particularly interested in high pressures and in the properties of substances at the critical temperature, on which he contributed papers to the Royal Society.

Hannay's work on diamonds[7] arose from his studies of the power of gases, especially water vapour, to dissolve solids under very high pressures, and he thought that if carbon could be brought into solution in some gas under high pressure, it might crystallize as diamond on cooling. In his first experiments he heated hydrocarbons with lithium in sealed glass tubes, the object being to bring about thermal dissociation of the hydrocarbon, absorbing the hydrogen produced in the alkali metal. Crystals which would scratch glass were occasionally obtained, and as these were octahedral, optically isotropic, showed the characteristic curvature of the faces, resisted hydrofluoric acid, and burnt in oxygen, he concluded that they were true diamonds. However, he thought it advisable to use higher temperatures and pressures than could be reached in glass tubes, and a change was made to tubes of wrought iron. The tubes were 20 in. long and ½ in. bore, but the thickness of the walls, at first only ¼ in., had to be progressively increased to more than 1½ in., on account of bursting. Various plugs were tried but invariably leaked. It was found necessary to close the open end by a blacksmith's weld, the modern methods of welding not having been invented, and as this had to be done on a short length of tube two thirds filled with volatile liquid, it is not surprising to read that "It requires great skill on the part of the workman, and it is only one man in a hundred who can perform the operation with invariable success". The sealed tubes were heated in a coal-fired reverberatory furnace. All but a few of the tubes burst during heating to redness; and as on many occasions the furnace was wrecked and had to be rebuilt, Hannay's perseverance must be considered as extraordinary. Out of more than eighty experiments only three were successful. Tubes bored from solid steel bars failed badly.

Hannay had been seeking commercial uses for 'bone oil', a mixture of nitrogenous compounds obtained by distillation from bones, and this occurred to him as a possible solvent for the experiments on diamond. Its volatility (the fraction boiling between 115° and 150° was used) made welding still more difficult, while "the continued strain on the nerves, watching the temperature of the furnace, and in a state of tension in case of an explosion, induces a nervous state which is extremely weakening, and when the explosion occurs it sometimes shakes one so severely that sickness supervenes". In spite of these difficulties, Hannay obtained some positive results, using a mixture of 90 per cent of "paraffin spirit" and 10 per cent of bone oil with the addition of solid lithium. The hard residue was crushed, and was found to contain some transparent crystals which were identified as diamond. A combustion carried out on 14 mgm. gave 97·85 per cent of carbon.

In spite of the small number of successes, it is difficult to believe that Hannay was mistaken in his identification. As his solid residues contained nitrogen, he was inclined to believe that the diamonds owed their origin to the nitrogenous compounds used and not to the hydrocarbons, a point which would have an important bearing on the origin of the natural crystals. Although he announced his intention of making further experiments, no later paper on this subject appeared, although he published work on other subjects so late as 1894.

Moissan attempted to repeat Hannay's experiments, but could not succeed in welding the tubes. Parsons also tried the same materials and pressures, but without success, and the work might have been forgotten but for the fortunate fact that twelve of the minute crystals obtained by Hannay in 1879–80 had been deposited in the mineral collection of the British Museum (Natural History). None of the crystals obtained by either Moissan or Parsons has been traced.

The whole subject has been transformed by recent work with X-rays. Mrs. K. Lonsdale and Mr. F. A. Bannister[8] were able to examine by X-ray methods the crystals preserved at South Kensington, and found some of them to be true diamonds. What, however, was still more remarkable was that they showed the characteristics of the rare (type II) diamond described by Sir Robert Robertson and his colleagues[9], which differ profoundly in optical and electrical properties from the normal type I. One was definitely identified by its X-ray pattern as of type II, while the others showed the highly laminated condition which is associated with that type. Since type II only occurs in about one per cent of natural diamonds, the probability that Hannay's crystals were actually obtained artificially is greatly strengthened, and the accuracy of his statements vindicated. It is clear that the new observations re-open the whole question, and that, in spite of the failure of Parsons and Duncan to convince themselves that they had obtained true diamonds, and their consequent rejection of earlier work, it may prove that the methods of high pressure and high temperature common to the work of Hannay, Moissan and Parsons do actually succeed in converting a minute proportion of the carbon contained in the materials into diamond, although the factors determining such a transformation remain very obscure, while the fact has to be borne in mind that all diamonds, exposed to a sufficiently high temperature, are changed to graphite. A very old problem thus comes again into prominence, but with the advantage of experimental methods of rapid identification which were not available to the earlier workers.

NATURE AND USES OF SEAWEEDS*

By R. E. MARION DELF

Westfield College, University of London

IN the last fifty years or so there has been much progress in our knowledge of seaweeds, but until comparatively recently, mainly from the botanical point of view. Until this century, botanists had been chiefly concerned with nomenclature and with the major facts of structure and reproduction of a few commoner types. But early in this century, newer lines of investigation were being developed, involving the systematic analysis of vegetational units and the study of the complex relations between the plant and its environment. Mr. A. D. Cotton has made an ecological survey of the marine algæ of Clare Island, off the coast of Ireland. This study, the first of its kind by a British author relating to the algæ, became and has remained a classic for other workers in this field.

Another and rather different line of advance during the last thirty to forty years has been in the study of the life-histories of the marine algæ, stimulated in Great Britain by the work of Lloyd Williams (1906) and in France by that of Sauvageau (1915). Lloyd Williams found that in the brown alga *Dictyota dichotoma*, Lamour, two generations, externally similar, followed one another, each devoted to a different kind of reproduction, one with sexual, the other with asexual reproduction. He also found a definite rhythm of reproduction, closely related to tidal phenomena. Sauvageau made the even more striking discovery that the innumerable swimming spores produced by the different species of Laminaria (reckoned by Yendo as about 84,000 per square millimetre) could be made to germinate, when they developed into minute branched threads requiring high magnification for observation. These ultimately gave rise to gametes, which after fertilization reproduced the early stages of the original type of plant.

The effect of this discovery on the botanical world was far-reaching. It has been found that this type of alternation is characteristic of the whole family of Laminarias, though by no means limited to it. In many apparently annual types, like the familiar 'sea bootlaces' (*Chorda filum*, Lamour), although the visible thallus or 'bootlace' dies down at the end of the summer, a microscopic sexual generation is produced and carries on the cycle unseen beneath the waters during the winter months.

In respect of the red algæ, Yamanouchi followed the still more complicated life-history of *Polysiphonia violacea*, Harv. (1906), and this became the forerunner of many similar investigations, notably those of Svedelius (of Copenhagen) and of Kylin (of Bergen). Although most red algæ have alternation between two similar plants, it is beginning to be realized that others have great difference in form between their alternate generations, even when both are equally visible to the naked eye. To establish their identity is then no easy matter, for most marine algæ are difficult to cultivate under artificial conditions. It is not surprising that nomenclature of the marine algæ is in a backward state, since in the past it has been founded largely on the observation of material (often dried) apart from a knowledge of life-cycles,

---

[*] Substance of a paper read before the Royal Society of Arts on May 12.

or of other differences in form brought about by the influence of a particular environment. There is, as yet, no systematic record of the algal vegetation of our coasts. Such accounts as are available relate to particular localities, usually to summer resorts where rocks are relatively accessible, or to regions within the sphere of influence of marine biological stations, like that at Plymouth or at Port Erin, in the Isle of Man. Little is known of the interaction between the animal and plant population of the shore.

Whereas some seaweeds are permanently submerged in pools or in deep water, the majority are amphibious, in that they spend part of their lives under water, part exposed to the air, owing to the receding of the tide. Unlike some amphibious animals, they are fixed to some substrate, so that they must endure, at least temporarily, all atmospheric vicissitudes. They may be heated by the sun, cooled by wind or frost and dried by the action of wind and sun together. The sea-water adhering to them may be diluted by rain or concentrated to brine by evaporation. The time of exposure varies with the height of the tide and the position on the shore. Those near the upper limits have longer exposure, and unless they are to be found in fairly deep pools, only species which are resistant to desiccation can survive in this region. For the same reason, in hot climates, intertidal vegetation is much more sparse than on temperate shores. The middle regions of the shore are the most densely populated by both animals and plants, and here competition for space and light is the keenest; while at the lower limits, the depth of water is such that there is too little light for any but shade plants (mostly red algæ) or brown ones like the Laminarias with long stipes which bring the flat fronds up towards the surface.

On the whole, in temperate climates there is a marked tendency towards zonation—at low water, the higher and middle regions of rock or shore being predominantly brown, from the more numerous of brown algæ, the lower regions red or brownish-red. The underlying causes of this zonal distribution has of recent years been the subject of much discussion.

All this is not merely of general or academic interest. If, as seems not unlikely, seaweeds may become an asset of some commercial importance, conditions of their growth, regeneration and harvesting must be more fully explored. In suitable localities and on suitable shores it may then be worth while to cultivate the more profitable kinds. Something of the kind is, indeed, already being attempted on a small scale in the so-called Fucus farms of Northern Ireland, where the harvest is utilized locally for manuring the fields. These farms are located in somewhat sheltered bays where, at low water, there is a flat stretch of sand strewn with large stones, boulders or rocks. The kind of alga which develops depends partly on the nature of the anchorage, partly on the position with respect to tidal range. Thus the boulders and larger stones of the upper middle tidal zone become covered with Ascophyllum; the smaller stones wedged between bear *Fucus vesiculosus* L., the common bladder wrack; while at lower levels both stones and rocks bear *F. serratus* L.

These three species form the bulk of the harvest, and when cut are regenerated from sporelings; but apparently two or three years must elapse between successive harvests from the same area, and no attempts have been made, so far as I know, to improve the yield or to shorten the period of regeneration and maturation; more stones are sometimes added, however, and this demands a certain amount of judgment as to size and suitability. At the present time, a number of research workers at Port Erin are engaged in studying the growth-rate and reproduction of certain seaweeds of possible future importance with a view to their more rational harvesting, and it is to be hoped that these and other investigations will be continued and expanded in post-war years.

Seaweeds have been used extensively in the East for many years; in Japan especially for food, manure and glue. Early in this century, when commercial developments were visualized, a definite cultivation was inaugurated there. For this purpose, suitable rock-surfaces were cleared of weed during the period of reproduction. After a time, the water being full of their spores, a new crop appeared, which successfully established itself in spite of competition with other kinds which usually arrived first.

The Japanese botanist Yendo was instructed to study and report on the conditions for success and also on the causes of failure in certain areas. With the help of this report and the practical experience of fishermen who were employed in the cultivation, instructions were drawn up and circulated as to planting and harvesting the appropriate seaweeds. On certain reefs, constantly removing crops of Laminaria favoured the spread of a useless plant, Phyllospadix (one of the few submarine flowering plants), which covered the surface with its undergrowth and smothered the young plants of Laminaria. The removal of the Phyllospadix was therefore made compulsory, a special tool being designed to facilitate the periodic weeding.

Yendo pointed out that seaweeds, like other plants, had their peculiarities which must be considered: for example, Gloiopeltis, from which much glue is made, flourishes best on smooth, hard surfaces, in positions where there is spray or foam; on the other hand, rough surfaces suit most seaweeds, Laminarias requiring a hard rock, like quartzite, pitted with numerous depressions. Porphyra is grown by planting small twigs obliquely in crevices in areas where the salinity is high. This gives the greatest number of sporelings: the twigs are then transplanted to places where the salinity is lower, in order that the finest fronds should develop from the sporelings.

Not all marine plants are seaweeds in the stricter sense of the word. Zostera, the eel-grass, for example, which occurs in relatively quiet waters, is a flowering plant, producing flowers and fruits beneath the waves. The true seaweeds, on the other hand, are plants of a much lower order in the evolutionary scale of plant life, as will have been realized in connexion with the life-cycles to which reference has already been made.

The great differences between the marine algæ and the flowering plants are seen, however, in many other features—for example, in their general organization, the plant having no root system, no buds or flowers, and, of course, no seed production. It is also seen in their construction, which has little in common with that of flowering plants even when these, like Zostera, have the same habitat.

The building of a structure may be said to depend on three things—on materials, the building unit and on design. The building materials of the seaweeds are various mucilaginous and gelifying substances, cellulose playing little or no part in the composition of their walls. The unit of construction is the branched thread or filament, that is, a chain of cells rather than single cells aggregated into tissues. The whole structure is fabricated of variously interwoven threads, some of which may have walls of considerable thickness. Some of the threads send out lateral branches, the tips of which become compacted together, giving a firm exterior to the plant. In many surf plants, the threads become intricately intertwined, as the thallus is tossed about by wave action. Mucilaginous substances, believed to be derived from the cell walls, cement the whole together. The architecture of most seaweeds is such as to give flexibility with either elasticity and extensibility as in Ascophyllum and Himanthalia, or with a certain tensile resistance as in Fucus. The peculiar wall material also serves another purpose, readily absorbing water and retaining it with tenacity when exposed to drying. It is these wall substances which promise to become of great commercial importance.

The biochemical features of algal products have been explored from several angles—their pigmentation, their metabolic products and their wall substances differing considerably in the three great groups. Most of this lies beyond the scope of the present paper; but I should like to note in passing the success of a plant biochemist, Dr. Paul Haas (1931), in capturing and identifying the source of the characteristic smell of one of the common red seaweeds, *Polysiphonia lanosa*, parasitic on the brown alga *Ascophyllum nodosum*. The fresh alga was placed in a flask, kept at 30° C. by means of a water bath. Air was drawn through and carried over a volatile substance, which dissolved in water, alcohol or acetone. Afterwards this was found to be identical with methyl sulphide.

Utilization of Seaweeds

Generally speaking, seaweeds are utilized in three principal ways: in connexion with agriculture, as food or medicine, and for industrial purposes.

1. *Seaweeds in agriculture*. In agriculture, seaweeds are used as fodder or as manure. The seaweed may be fed fresh (sheep, for example, are allowed to graze on the rocks at low water in the Orkneys). In the north of Scotland, Pelvetia is brought to the boil and after addition of oatmeal is used to feed calves. Dried seaweed, ground to a meal, is used in some districts or, alternatively, the fresh seaweed is stored in layers with hay between, forming a kind of silage as winter feed. *Laminaria saccharina* was fed to horses with varying success in France during the War of 1914–1918. Reports of the results are not always in accord, perhaps because of seasonal variations in the food value of the alga, since the sugar content is at a maximum in the autumn and it seems that the sugar (stored as laminarin) is probably the most easily digested of the constituents. In New Zealand, seaweed (Macrocystis, Hormosira) is found to benefit cattle grazing on poor pasture land. In America, seaweed meal has improved health and fertility in cattle and in chickens, when fed as a small proportion of the daily diet.

The use of algæ as manure in maritime situations is widely practised. It is well known on coasts of Brittany, on various coasts of Ireland, in the north and west of Scotland and on coasts of northern Europe. Naturally, driftweed is largely collected for the purpose, but harvesting the cut seaweed is also practised where the coast is suitable. In north-west France the collection of algæ has been regulated by statute for some hundreds of years. The manurial value is probably due to the organic constituents, which provide bulk for the soil, as well as for the mineral salts. There is little nitrogenous value in most seaweeds, but the different kinds of laver (Ulva and Porphyra) are said to be exceptional in this respect.

2. *Seaweeds as food or medicine*. The use of seaweeds for food has been known from very early times. They are greatly valued in the East—in Japan, coasts of China and Malay; but they are also used on the north and north-west coasts of Europe.

Laver (*Ulva latissima* and *Porphyra laciniata*), dulse (*Rhodymenia palmata*) and murlins (*Alaria esculenta*) are eaten as vegetable on the coasts of Ireland and Scotland and no doubt elsewhere, and may be familiar in this capacity to a number of people. The name of sea lettuce for *Ulva latissima* is suggestive.

Pink laver is produced commercially in Japan, and the washed, pressed fronds are regarded as a delicacy. It is used under the name of *akusanori* for soups, as a vegetable, or may even be eaten raw. The sample I happen to possess claims to be especially fine—but it seems rather tasteless to the Western palate. In Great Britain, probably carrageen moss (*Chondrus crispus* and Gigartina spp.) is the most widely utilized of seaweed products, valued for the jelly-like nature of its hot-water extract. In the War of 1914–18, carrageen was in demand to replace gelatin, which was in short supply.

Little seems to be known with any certainty as to the food value of even the most edible weeds. It is usually considered that their mineral content is of value, especially the iodides, which are characteristic of many brown and some red kinds; their gelatinous substances are probably not digested by man, but may be useful in providing bulk without irritation. There are algæ like *Laminaria saccharina* and *Alaria esculenta*, which seasonally store sugars, but it seems doubtful whether these particular sugars can be digested, at least by human beings. It is on record, however, that the digestive juices of snails and limpets are very efficient in this respect.

Seaweeds as food have never been very popular in England, but several preparations are marketed at the present time and sold as "seaweed salt". This is recommended as giving a daily quota of iodine in natural form, to maintain health or to correct deficiency in those with a tendency to goitre. Some of these preparations claim to be the dried and finely powdered weed. In conformity with this claim, the powders, on moistening, swell to a gelatinous mass which has a taste decidedly suggestive of seaweed. The iodine content of certain seaweeds is remarkable in that it has to be derived from the sea water, in which only traces occur. The algæ are believed to absorb water over their whole surface; they must have the power not only to absorb the traces present, but also to accumulate them within. The physiological mechanism of this accumulation is little understood.

Among the brown algæ, the Laminariaceæ are relatively rich in iodine, but the Fucaceæ are also used as sources of iodine in some localities. A number of red algæ also store iodine (for example, species of Iridea and Asparagopsis), while a few have special enlarged superficial cells rich in iodides: these red algæ, however, do not occur in sufficient abundance, at least in Europe, to serve as a source of iodine on any commercial scale.

3. *Commercial products.* The manufacture of potash and other substances from kelp* (derived from the larger brown algæ) fell into disuse in the latter part of the nineteenth century, when cheaper sources were discovered from mineral deposits. In the present century, interest has grown in the algæ as a source of mucilaginous substances utilized in many ways, especially in Japan, Great Britain and the United States. These mucilaginous substances can be divided roughly into two classes with differing chemical and physical properties: those from the brown and from the red algæ respectively.

The mucilaginous products of the higher brown algæ can be extracted by boiling the fresh material with a dilute solution of sodium carbonate. After a time, the tissues swell and lose their shape; the mass is then filtered through cloth, and on acidifying there forms a thick, slimy substance recognized by Stanford in 1862 as of definite chemical composition and named by him first algin, later alginic acid, since it formed a series of metallic salts, like a true acid.

In recent years, algin and its derivatives have been utilized for many commercial purposes. A study of the many patents granted in this period reveals something of the progress which has been made both on the technical side and in the chemical knowledge on which that progress must be based. It has been found, for example, that when treated with vulcanizing agents, such as carbon disulphide or carbon tetrachloride, algin becomes a rubbery mass, which has been used to make rollers for typewriters, among other things.

By violently agitating an alkaline solution of algin with which a small proportion of tannic acid has been mixed, the whole emulsifies and may be poured upon a glass or polished surface, giving a transparent film resembling 'Cellophane'. It is claimed that this film is cheap, almost non-inflammable and less influenced by light than true 'Cellophane', which is apt to become very brittle. It has already been widely used as an inexpensive transparent wrapping for various classes of goods, or, at least, it was so used before restrictions on wrappings were in force.

The purified alkaline extract of the fresh seaweed may, alternatively, be forced through a fine aperture, forming a viscous thread which is then spun into a bath containing a mixture of furfurol, caustic soda, formalin and other substances. By this means a kind of 'artificial silk' is produced, which after further treatment is washed and finally sized with an ammoniacal solution of algin under pressure.

This thread, however, as first produced, was not strong enough for weaving, and moreover was not sufficiently resistant to soaps containing a proportion of alkali. Further processes involving treatment of the thread with salts of chromium or beryllium are alleged to have overcome these difficulties. The chromium salts, being coloured, were not so suitable for subsequent dyeing, but the beryllium salts appear to be free from this objection. The strengthened thread so obtained will, no doubt, be tested in due course for weaving.

The Japanese claim to have produced an artificial wool from gulfweed (Sargassum spp.) by spinning the viscous thread into a bath, which had a crimping effect.

In recent years, salts of alginic acid have been obtained from species of Laminaria collected on the Atlantic coasts of Scotland. From this source, the firm of Albright & Wilson have been able to market a purified form of sodium alginate which has been given the trade name of 'Manucol'. The white powder dissolves in water to form extremely viscous solutions which are tasteless, odourless and almost colourless. It is claimed that these powders or their derived products have been utilized in connexion with a variety of industries, including production of food and medicines, and the manufacture of cosmetics, textiles, transparencies and plastics.

Alginates may be added to milk previous to the manufacture of milk powders; in this way, the milk can be reconstituted by the addition of water, without causing sedimentation. Cocoa may be rendered more 'soluble' by a similar addition.

The colloidal properties of alginates render them especially suitable as a base for creaming agents, for car polish and even for boiler feeds to prevent the deposition of 'fur'. In these and a number of other commercial products, alginates behave as 'protective' colloids, helping to keep in suspension or emulsion particles which would otherwise tend to settle as a sediment.

Although so many uses have been found for the salts of alginic acid, the chemical composition of the acid itself has been a subject of controversy. Stanford concluded that the molecule was a large one, including nitrogen ($C_{76}H_{80}N_2O_{22}$), but later work with purified materials has established that it is a polymer of *d*-mannuronic acid. Experiments of Bonniken appear to indicate that treating the alkaline salts with astringent agents causes a progressive polymerization of the original algin molecule, giving longer and more complex chain structure. It is these long-chain molecules which are important for the production of textile threads and are susceptible to contraction, giving the possibility of a crimping effect.

Two classes of colloidal substances can readily be extracted from red algæ, namely, mucilages and gels. The former may be dissolved out with cold or tepid water, the latter by boiling for a short time.

In Japan, at Osaki, a kind of seaweed glue called 'funori' is made from species of Gloiopeltis (chiefly *G. coliformis* and *G. intricata*). It is used for adhesives and for sizing paper, fibre or cloth. A more valuable product is agar-agar, the commercial name given to the gelatinous substance extracted by boiling water. During the last two decades, agar has been widely used in connexion with foods and medicines. As a laxative, it absorbs and retains water, besides acting as a lubricant. It is almost universally used as a basis for bacterial and fungal cultures, resisting liquefaction. Recently, however, a strain of bacteria, *Vibrio agarlyticus*, has been isolated which liquifies agar but not cellulose.

By far the greater part of the world's supply of agar came from Japan, but a considerable quantity has also been manufactured in California, though much is not sufficiently pure for bacteriological purposes. At the present time, investigations are being carried out in the United States and other countries, with the view of developing local supplies. The rich algal flora of the coasts of South Africa and New Zealand and of the west coasts of North America and Canada offer many possibilities, but even in the U.S.S.R. during the last ten years, an agar-producing industry has apparently been developed, utilizing algæ which occur on their maritime coasts and on the shores of the Black Sea. It has recently been announced that agar suitable for bacteriological purposes has been obtained from certain seaweeds in South Africa, New Zealand and in Britain. This is being further explored.

---

* 'Kelp' was the name originally used for the ash of the larger brown seaweeds after burning. In America it has also been applied to the various brown algæ used for this purpose.

To obtain a pure agar, the freshly collected algæ are bleached in the sun for some days, the process being hastened by sprinkling at intervals with fresh water. The bleached algæ are then boiled with water (Japan) or treated with steam (United States) and the resulting mass strained through cloth. The clear liquid is poured into shallow troughs to set, and the jelly cut into narrow strips. In Japan, the process is carried out in cold weather, so that the strips contract, expelling water ; in the United States the same result is obtained by artificial refrigeration. In either case, the expelled water is drained off, and the remaining jelly dried and shredded for packing.

Agar prepared in this manner has been analysed and is described as "a galactan with sugar units of unusual structure". Carrageen mucilage from *Chrondrus crispus* is a "polysaccharide ester of sulphuric acid by the acetolysis of which two galactans were isolated". Both these products are water soluble. According to Tschudy and Sargent, the two American species of Gigartina require a preliminary soaking and subsequent boiling in lime water or 2 per cent calcium chloride in order to extract a substance giving a firm jelly. Subsequent treatment (straining, cooling and drying) appears to be the same as for the water-soluble derivatives of other types. It appears, therefore, that a number of different but probably closely related substances with similar physical characteristics are included under the general term agar. The amount which can be extracted appears to be very variable. One of the best sources, the Japanese *Gelidium amansii*, is said to yield 25–35 per cent of its dry weight as agar.

The commercial utilization of seaweeds raises many issues. Having regard to present difficulties of overseas transport, it would seem natural to seek supplies from our own shores, possibly from the west and south-west of England, and the west and north-west of Scotland. The shores must be far enough from towns to escape serious pollution from sewage, yet sufficiently accessible to the collector and to transport for the material collected. For most purposes, probably, the dried seaweed would suffice, and it could be washed and dried on the spot, before packing.

When harvesting is regularly practised, it may be necessary to restrict the season of cutting and to regulate it in such a way that regeneration may occur by natural means. Much more information is needed as to the requirements of seaweeds for healthy growth and the reasons underlying the present distribution, especially of useful types. It is very probable that advances along these lines would lead to successful cultivation of desirable types like *Gracilaria confervoides, Ahnfeldtia plicata* or *Gelidium corneum*, which are fairly common in some localities, or of *Chondrus crispus* and *Gigartina stellata* Batt., which are already known to be abundant in certain areas.

The commercial utilization further demands much work on the biochemical and technical side before the final stages of marketing can be reached. We thus require the services of the botanist, the ecologist, the biochemist, the technician and the financier. Yet the last word remains with the botanist, who combines the experience and judgment of a systematist with the practical knowledge of the ecologist. For, in order that analyses may bear fruit, it is necessary that the right type of alga should be recognizable and recognized, its course of life understood and its reproductive periods utilized to the full.

PHYSIOLOGY OF THE LUNG

By DR. O. A. TROWELL,
University of Edinburgh

PROF. B. Narayana, in his presidential address to the Physiology Section of the thirtieth Indian Science Congress held in January last, took as his subject "The Growth of Physiology as an Experimental Science". After tracing the history of experimental physiology from its origins with Ludwig and Claude Bernard, and giving some account of its current status, he proceeded to a review of recent work on the vasomotor and bronchomotor mechanisms of the lung, which subject he chose as an illustration of modern methods and the modern outlook in experimental physiology. This field of research has been developed chiefly by Prof. de Burgh Daly and his colleagues, first in Birmingham and later in Edinburgh. Prof. Narayana himself collaborated in some of the work in Edinburgh, and later he and his colleagues in India have made further contributions of their own.

In considering the physiological activity of the lung itself, we may remark that its respiratory movements are merely a passive response to changes in the capacity of the chest, that the gas exchange between blood and air is simply a process of physical diffusion, and that the only known physiological variables intrinsic in the lung itself are the calibre of the blood vessels and the calibre of the bronchi. The calibre of these tubes is controlled by the plain muscle fibres which form a large part of their walls. Vasomotor and bronchomotor changes, therefore, seem to be the principal intrinsic activities of the lung which call for investigation, and this is the field which Daly and his colleagues have successfully explored.

In the physiological investigation of any bodily organ there are, broadly speaking, two alternative lines of attack available. The first, or analytical, method seeks to isolate the organ in question from the disturbing influences of the rest of the body, preferably by excising it altogether, and, keeping it alive under fully controlled but somewhat artificial conditions, to analyse its functional responses to controlled stimuli. The second, or synthetic, method seeks to establish the part played by the organ in the integrated life of the whole animal, how it influences, and is influenced by, changes occurring elsewhere in the body. In the first method natural conditions must be sacrificed in order to secure full experimental control, and the results obtained indicate the physiological potentialities of the organ rather than its normal behaviour in the whole animal. The second method sacrifices full experimental control in order to maintain a natural condition of the organ; the results generally lack the scientific certitude associated with the former method, but when significant they reveal more truly the role of the organ in the normal life of the animal.

Daly, in his work on the lung, adopted the analytical approach. His success has been due in the first place to the development of a skilful technique whereby the lungs can be removed from the body and kept alive for several hours under artificial conditions, the blood circulation and respiratory movements being maintained by suitable pumps. The lung inflation, blood pressure, blood flow and other factors were under complete control and were recorded continuously. A second factor, no less essential to success, arose from an anatomical consideration. It was known that in addition to their main supply from the pulmonary artery, the lungs also receive a small vascular supply from the systemic circulation by way of the bronchial arteries. These vessels supply the walls of the bronchi and those of the pulmonary arteries together with their associated nerves and ganglia. In preliminary work, Daly traced the territorial distribution of the bronchial vascular system in the lung; he showed that there is a capillary anastomosis between the bronchial and the pulmonary circulations in the region of the respiratory bronchioles, and he was the first to realize the physiological importance of the fact that the arterial and bronchial musculature, with their associated nerves, the very tissues the responses of which were to be the subject of investigation, received their oxygen supply and nourishment exclusively from the bronchial circulation. He therefore devised a method for the separate perfusion of the bronchial circulation as well as the pulmonary circulation in the isolated lung. Previous workers on the isolated lung had perfused only the pulmonary vessels, and their usual failure to obtain vasomotor responses was therefore only to be expected. The technique of the 'isolated perfused lung' had to be perfected before any worthwhile investigations were feasible.

The results obtained have provided convincing evidence of the existence of a nervous vasomotor control of the pulmonary circulation; the earlier evidence had been unsatisfactory. The vasomotor and bronchomotor responses to the stimulation of various nerves and to the injection of various hormones and drugs were fully investigated in several species of animal—guinea pig, cat, dog, pig and monkey. The particular responses obtained varied considerably from species to species and also under varying experimental conditions in any one animal, so much so that no simple or uniform picture emerges. This is characteristic of modern physiology; the more intensively a phenomenon is investigated the more complex is it revealed to be, and the final picture ever recedes from sight. Every day the apparently simple phenomena of classical physiology grow more and more complex as they are subjected to the more searching analysis of modern technique.

With regard to the vasomotor responses, stimulation of either cholinergic (vagus) fibres or adrenergic (sympathetic) fibres most commonly produced vasoconstriction, but in certain defined circumstances vasodilation could result from either. Injection of acetyl choline or adrenaline gave parallel results. The bronchomotor responses were similarly variable, depending on the species and the experimental conditions. The detailed findings are of considerable interest, particularly in their relation to current theories of chemical transmission in the autonomic system, but space does not permit their discussion here.

Perhaps the most significant outcome of this work is to be found not in the detailed findings, but rather in the very variability of the responses obtained; the fact that a given nerve or a given hormone can produce in certain circumstances a constriction and in other circumstances a dilatation in one and the same preparation is in itself of the greatest physiological importance, and suggests many hitherto unthought-of possibilities with regard to the occurrence of similar changes in the whole animal. The problem of the bronchospasm in asthma, for example, can be considered in quite a new light as a result of these researches. It must always be remembered, however, that the isolated perfused lung is surviving under highly abnormal conditions and probably its behaviour is correspondingly abnormal; so the transference of these results to the whole animal and to man is at present not justified. The potentialities of the lung have been revealed; to what extent they operate in normal life remains to be discovered.

Prof. Narayana concluded his address with a plea for the further development of experimental physiology in India. He himself is already contributing to this end in the active research which he has initiated in his own department at the University of Patna. We can wish our Indian colleagues well in their pursuit of the common ideal, and we shall look forward to their contributions to the further growth of the science.

OBITUARIES

Mr. William Hartree, O.B.E.

A REMARKABLE fact about William Hartree, who died on April 27, 1943, was that his first scientific paper appeared (in 1920) when he was fifty, his last (in 1941) when he was seventy-one. In those twenty-one years he published ten papers alone and thirty-six in collaboration (in *J. Physiol.*, *Proc. Roy. Soc. A* and *B*, *Phil. Trans. A* and *B*, *Phys. Rev.*, *J. Sci. Instruments*, *Proc. Camb. Phil. Soc.*, and *Biochem. J.*).

In the strictest and best sense, Hartree was an amateur; he worked for love of his work and, I think one dare say, of his collaborators. But he worked also with the intensity and pride of a craftsman in his job, and for all his steadfast modesty, he knew, like a craftsman, when he had done it well, and he worked with quite inflexible devotion. During the War of 1914–18, at Whale Island, he said —almost seriously—that he was going on strike for more work and less pay: his pay could not have been much less nor his work more. I had to stop him then from trying to get into the army at forty-seven —because he was enjoying that work too much! Later, at Cambridge, when I pressed him once to take a holiday, he wrote me next day "I have taken a holiday to-day—made a new kind of experiment"—the only kind of holiday he liked.

Hartree was known, except by his work, to very few: he never attended meetings: he wanted no credit or praise for what he did. He almost seemed to prefer to do a difficult job well rather than make it easy. He was ready to face the most laborious calculations in order to obtain a result; he almost resented at first any improvement in technique which made calculation simpler. In his work with me on the physiology of muscle he reckoned that he had written down between 10^7 and 10^8 figures, and we very seldom discovered a mistake. He was always ready to take a sporting chance to see what he could make of a new job—as when he took up research on A.A. gunnery in 1916, when he turned (a mathematician and engineer) to experimental physiological research in 1919, when he took to the theoretical study of atomic structures in 1933 and to the numerical solution of certain partial differential equations, concerned with motion in a viscous fluid, in his last years. Yet in some ways he was very conservative; for thirteen years his chair in the physiological laboratory at Cambridge, where he did his arithmetic, was precariously balanced on four old fuse-tins of the last war, when it would have been easy to lengthen the legs or even to screw the fuse-tins on ! He was not an original or brilliant thinker, though he was obstinately independent when he knew he was right ; he preferred always to help others, and this note is written, in gratitude and affection, by one whom he helped full-time for seventeen years.

Hartree was born on April 8, 1870, the son of John Penn Hartree, F.R.C.S. His mother was the daughter of Samuel Smiles, author of "Self Help" (1859) and many other works. J. P. Hartree was the son of an able engineer and, like his son, was educated at Trinity College, Cambridge ; he obtained a first-class in the Natural Sciences Tripos (1865). Later he practised, and attended various hospitals in London, but when his son Willie was six years old moved to Belfast. He passed on his temperament and abilities to his son : retiring, silent, able, kindly, with the same high standards and perfection of work. He was a well-known member of the Alpine Club.

From Belfast, W. Hartree went to Tonbridge School and later to Trinity College, Cambridge, where he was eighteenth Wrangler in 1892. Then after a short apprenticeship in electrical engineering he lectured and demonstrated in the Engineering Department at Cambridge until 1913. He married in 1895 his cousin Eva, daughter of Dr. Edwin Rayner of Stockport (sometime treasurer of the British Medical Association) and of J. P. Hartree's sister, and sister of Dr. E. H. Rayner, late of the National Physical Laboratory. Mrs. Hartree has been mayor of Cambridge (his friends always wondered what sort of 'mayoress' Hartree made !) and has done distinguished public work in many fields. Of their five children, only one survives (Prof. D. R. Hartree of the University of Manchester) ; a younger son who had been a 2nd lieutenant in the Royal Artillery and had worked, like his father and brother, at Whale Island on A.A. gunnery, died soon after the War of 1914–18.

In 1913 Hartree retired and went to live in Surrey, where he busied himself with experimental wireless. Early during the War of 1914–18, he joined up for work with the G.P.O. and served—with his usual devotion and humility—as a telegraph linesman. In 1916, when R. H. Fowler and I were starting up what later became the Anti-Aircraft Experimental Section of the Ministry of Munitions, Hartree, at E. H. Rayner's suggestion, came to join us. It was hard to believe that this shabby, middle-aged linesman, offering to work for love, was an able mathematician and engineer—but he was, and much more. Whenever a job of hard work had to be done on time, whenever some difficult observations were to be made, whenever something was to be fetched or carried, whenever long hours and discomfort to be endured 'at the far end of the base', Hartree was there. Nobody could see shell-bursts so nearly into the sun, nobody could record what he saw so accurately and quickly, nobody could interpret the results so well, nobody would come so early to the office or stay so late to work them out. Quietly, one day, he improvised a long-base height-finder out of some wires, posts and a steel tape. It came to be called the Hartree height-finder and was used extensively by the troops until sufficient monostatic optical height-finders were produced ; perhaps that was why he was given an O.B.E. Once he was arrested on the beach near Great Yarmouth during a gun-trial, for communicating with the enemy by means of an ordinary field telephone laid along the shore. Once, he was driven to writing verse because the captain of a monitor refused to fire his A.A. gun on a Sunday, the only fine day for three weeks. On Christmas Day 1918 he sent me the four volumes of his grandfather's book "Lives of the Engineers", with a note thanking me for my kindness. Everyone else—by then we numbered forty or so—knew who ought to be thanked.

When it was all over, the arithmetic finished and the instruments packed up, Hartree came to me with a long face and said it was a bad business ; he had never enjoyed anything so much, now what could be done about it. Having no intention myself but to return, after nearly five years absence, to physiology, and being young enough to believe that I could (it will be harder this time), I said "Why not come and do physiology at Cambridge ?" So Hartree was set to read Bayliss' "Principles of General Physiology", and in a few weeks returned and said that he had not known before that physiology was as interesting as that, and he would come ; which he did, for fourteen years. We started off in 1919 on the physiology of muscle, its heat-production, its dynamics, its recovery processes and its various peculiarities ; and Hartree learned to make and manage thermopiles, levers, galvanometers, oscillators and Ringer's solution ; and—what is much harder for an engineer—to dissect the muscles and nerves of frogs, tortoises and hedgehogs and keep them alive and working. The observations required skill and patience, and the records needed a deal of measurement and calculation—so much the better ! Hartree was the first to discover what ought to be called the 'Hartree Effect', that of after-exposure in intensifying photographic records.

I left Cambridge in 1920 for Manchester, moving to London in 1923, but Hartree carried on the work in Cambridge until 1933. On the physiology of muscle and allied subjects in that time came ten papers under Hartree's name alone in various journals, twenty-four under his name and others. We kept in continual touch by post and by as frequent visits as I could pay. I found him always either with his apparatus in a dark room, or perched precariously on his chair on the fuse-tins, doing the arithmetic ; never absent, however unexpected the visit. He arrived first in the morning, he usually left last at night—for love.

It would not be fitting, in such joint work, for me to assess its value ; but such value as others may attribute to it is due in large part to my collaborator—it certainly would not have been done without him. Some record of part of it is given in "Adventures in Biophysics" (1931).

By 1933 physical disability had made it difficult for Hartree to stand for the long hours necessary in the experimental work, and he felt also that the job which he had set his hand to in 1919 was more or less finished. He turned to his son, D. R. Hartree, for a new one. Fortunately, there were plenty of them that could be tackled at home, and of the kind that needed his patience, accuracy and planned methodical style. The main field of this work was in the calculation of atomic structures, but in the course of time he gave most valuable help in other fields, in particular in some exploratory work on a method for the numerical solution of partial differential equations, in the application of this method to the boundary layer equation in the motion of a viscous fluid, and in connexion with the gas flow in a tube. I gather from his son that his contributions to the practical calculation of atomic structures have been substantial and important. This work is not routine computing; it is essentially a matter of successive approximations, involving making and adjusting a set of estimates until a set of results, derived from these estimates by calculations which may take a week or two, agree with the estimates themselves; it needs understanding and judgment, far beyond that required for routine arithmetic.

The common experience of father and son at Whale Island, in trajectory and similar work, meant that they could talk the same language of methodical calculation, and another happy and fruitful collaboration developed, lasting until Hartree's death. Their joint papers are to be found particularly in *Proc. Roy. Soc. A*, from 1935 to 1939, while papers by Hartree and M. F. Manning are in *Phys. Rev.* 1940 and 1941. As D. R. Hartree wrote me, "I regard his work for Cu as a considerable technical feat; one aspect of it is that it forms the solution of a system of 34 simultaneous non-linear differential equations!"

This work with D. R. Hartree was done with the same "good companionship" (as E. A. Milne, another of the Portsmouth party, called it) as his previous work with others. "My father," D. R. Hartree writes, "once protested that he did not know the basic theory of the atomic work well enough to be cross-examined on that part of the papers, and so did not think that his name should appear on the title-page." Exactly the same diffidence had appeared in his earlier collaboration with others. "He would have been quite content with a formal acknowledgment at the end, and would not have been particular even about that. But his contribution in these papers was really the main one, without which they would not have been, and it would have been grossly unrepresentative of our relative contribution to the work if it had been published in papers under my name alone." As in physiology, so in atomic physics!

Hartree won a cup for fives at school, his handica at golf came down to four, he was a good hand a tennis and bridge, and his collection of 'postage paid postmarks is said to be unique in range and completeness. But of such things he never spoke. Fo many years before 1916 he had worked, no doubt, a methodically and as carefully as he did later; bu there is no printed record of the result. It is strang to think that the method of those ballistic calculation and carefully digested records of observations a Whale Island, and the 'good companionship' of th partnership there, could find so far an extrapolatio to physiology and atomic physics at the hands c this shy, gentle, kindly man. The greatest discoveries however, are made by keeping one's eyes open an one's mind alert for the odd things that turn up—i human relationships as well as science. Hartre turned up in 1916, and those who knew and worke with him since then are richer in both.

A. V. HILL.

WE regret to announce the following deaths:

Mr. W. R. Bousfield, K.C., F.R.S., an authorit on patent law, on July 16, aged eighty-nine.

Prof. H. L. Demler, formerly professor of physic in the Technische Hochschule, Dresden, later hea of the Department of Physics, University of Istanbu and finally visiting professor in Rutgers Universit on March 22, aged sixty.

Dr. Gerard De Geer, the eminent Swedish geologis aged eighty-four.

Mrs. E. C. V. Mattick, research worker in dair chemistry in the National Institute for Research i Dairying, Reading, on July 18.

Prof. E. P. Stibbe, University professor of anatom in King's College, London, on July 23, aged fifty-nin

Mr. Fred Stoker, the well-known horticulturist an author on gardening topics, on July 20.

NEWS and VIEWS

Prof. R. A. Fisher, F.R.S.

IT has been announced that the chair of genetics in the University of Cambridge is to be filled by the appointment of Prof. R. A. Fisher, who has been Galton professor in the University of London since 1933. Before that time he was head of the Statistics Department at Rothamsted Experimental Station. Prof. Fisher has been actively associated with genetics since 1918 when he showed that the biometrical correlations observed between relatives were to be expected on the Mendelian theory. He has written extensively on the action of selection, and he has shown that the manifestation of any gene must be regarded as modifiable through the action of selection on other genes in the nucleus. This culminated in his well-known theory of the evolution of dominance by selection and in his analysis of the genetical basis of mimicry and natural polymorphism. The mathematical theory of selection in relation to variation and mutation was further developed in "The Genetical Theory of Natural Selection" (1930), which also deals with the genetical aspects of human society. As would be expected, Prof. Fisher has been responsible for many improvements in the statistical analysis of genetical result especially in the methods of coping with the peculia difficulties of human data. His early work on th genetical interpretation and statistical analysis o biometrical data has also been extended, notably i a paper published jointly with F. R. Immer an O. Tedin in 1932. This work is perhaps less widel appreciated, largely because geneticists as a bod have been shy of attacking the inheritance of quantitative characters; but interest in this subject is reviving, and Prof. Fisher's findings must have thei influence on future developments here, as in othe fields. It is indeed singularly appropriate that h should both have succeeded Pearson in London an become professor of genetics in the University wher Bateson and his associates did so much to exten and amplify Mendel's results, for no one has playe a larger part in uniting the once conflicting science of biometry and genetics.

University of London: New Principal

MR. HAROLD CLAUGHTON has been appointe principal of the University of London as fro August 1, 1943. Mr. Claughton was educated a

Radley and Trinity College, Oxford. During 1906–1911 e was in India in the Imperial Record Department nd the Home Department, acting occasionally as xaminer in history for the University of Calcutta. He esigned in 1911 and for three years occupied himself vith literary work. He volunteered for active service 1914 but was rejected on account of short sight. n 1915 he was appointed to Military Intelligence, Var Office. At the beginning of 1919 he was appointed assistant secretary, and in November 1920 ecretary, of the Surplus Government Property Disposals Board. He resigned at the end of October 923 as the work of the Board was then practically ompleted. In 1924 he became financial officer and ecretary to the Senate of the University of London, vhich post he held until, in 1929, he was appointed he first clerk of the Court. During September 1939–anuary 1940 he was private secretary to the Minister f Information (Lord Macmillan). He then resumed is duties as clerk of the Court, acting as deputy to he Principal of the University from June 1940 until e became Acting Principal in October 1941. He was warded the O.B.E. in 1918 and the C.B.E. in 1923. He is also an Officier d'Académie Française.

conomics of Reconstruction in Britain

THE Oxford Pamphlet on Home Affairs, "Will the Var Make Us Poorer ?" by M. Young and Sir Henry Bunbury (Oxford University Press. No. H.5.; 6*d.* net), overs some of the ground of the Planning broadsheet 'Financial Mysticism" and is a valuable contribution o the lucid thinking required in the appraisal of the Beveridge and other proposals for post-war reconstruction. The authors point out that the only real limits on production are set by the available skill, equipment and organization, and that money for the individual and money for the nation as a whole have very different functions to perform. They also give warning against the restrictionism that involved us in disasters in 1919 and 1922, as well as against the anger of spending too fast after victory is won. Mr. Young and Sir Henry Bunbury then discuss three typical questions which the ordinary man is asking imself: Where does all the money come from ? Do rivate savings do any good ? Shall we be poorer after the War ? The clear answers given to these uestions lead to the conclusion that a few hard and difficult years may, provided we have vision and courage and seize our opportunities, lead us to a better and more securely based society than for many ecades. Good organization will be essential, including good monetary organization, with money not as controller but as a servant of human affairs. The uthors insist that we cannot again afford to waste ur resources of men and material; we cannot fford unemployment, or to lose great slices of our potential national income by wasting our resources. They are equally emphatic that the expenditure equired to rebuild Britain, to implement the Beveridge Plan, and to raise the standard and quality of living or the people of Britain, can be provided if our great uman resources are properly utilized and co-ordinated with the resources of other nations.

Water Requirements of Rabbits and Guinea Pigs

THE prevalent idea that rabbits and guinea pigs do not drink still persists widely in spite of all that has een written, said and broadcast. Prof. E. L. Kennaway directs attention to this false impression in a ecent issue of the *British Medical Journal* (1, 760; 943), where he reports that a 2·5-kilo rabbit on a dry diet will take approximately 160 c.c. of water, or 65 c.c. per kilo, daily, which is approximately twice the intake of an average human adult derived from both food and drink. It appears that rabbits fed mainly on a dry diet suffer from both water and food starvation, which is indicated by poor condition and scanty contents of the gut found post-mortem. If such an animal is provided with water, it takes a long drink and then greedily eats the dry food. It is obvious that water is essential for the normal physiology of the rabbit; the flesh (muscle and fat) of mature rabbits contains approximately 67 per cent moisture (King Wilson and Botham, 1934), being higher in males than females fed on similar diets. In comparative tests in feeding (*a*) dry mash and greenstuff, (*b*) dry mash and water and (*c*) dry mash, greenstuff and water (Christian, 1936) the best growth and development was obtained by (*c*), whereas (*a*) without drinking water caused impaction of the cæcum. Deprivation of water results in loss of appetite and a decline of 20 per cent in fur growth (Wirth, 1936).

Whether or not a rabbit will drink depends upon the moisture content of the diet; for example, a mixture of roots or potatoes and hay provides sufficient moisture (Brüggemann, 1937) for maintenance, whereas cereal grains and meadow hay required approximately 130 c.c. additional drinking water. When fed hay only, they drank about 150 c.c. of water but individual rabbits varied greatly (118–200 c.c.), requiring more in hot weather. Replacement of dry mash by fresh tea leaves in mixed diets resulted in a marked decline in water drinking (King Wilson, 1942). For production requirements the water supply is even more important. Although there is more dry matter in rabbit's than cow's milk, deficiency was seen to cause urine drinking and is one of the causes of cannibalism. Very similar results were observed with guinea pigs on restricted green-food diets.

Bell Laboratories Rubber Research Laboratory

ACCORDING to an article (*Bell. Lab. Rec.*, 21, No. 8; April 1943) by F. S. Malm, the Bell Laboratories have for many years been actively engaged in research on the chemical and physical properties of rubber and its compounds, to determine the kind of materials required to withstand severe weathering and the constantly changing conditions of temperature, humidity and light exposure. Most of the work has been directed to improving insulating materials made from plantation rubber, but an increasing part has been directed, during recent years, to synthetics such as Buna S and neoprene. Extensive studies have been carried out on insulation for submarine cables leading to the development of Para-gutta and pressure-equalizing materials for loaded telegraph cables. Insulation has been developed for coaxial cables and more recently dielectric materials for ultra-high frequency and micro-wave cables. Rubber jackets were also devised to protect against corrosion in the trans-continental cable being laid between Omaha and Sacramento.

About a year ago the Rubber Group moved to new laboratories at Murray Hill where complete facilities have been provided for studying rubber and its synthetic substitutes and for improving them. In anticipation of a peak load in this work additional equipment was installed including mixers, vulcanizers and apparatus for physical and chemical tests. All of this rubber-working equipment is provided with auxiliary apparatus for controlling and recording temperatures, pressures and power consumption. The laboratory rooms are unique in that any of fifteen different services including electric power, air pressure, vacuum, hot and cold water, hydrogen, oxygen and nitrogen in addition to illuminating gas are available at any bench or can easily be made so. To improve the desirable characteristics of a rubber material and suppress the undesirable ones the rubber research organization endeavours to relate the physical characteristics of elastic materials to their molecular structure. Special apparatus is used in studying what happens to the rubber molecules when they are compounded, vulcanized, and destroyed through use. These studies on the mechanism of vulcanization, viscosity, molecular weight and brittleness of rubber and allied substances are associated with current synthetic rubber problems.

Photography of Stars in Daylight

Many years ago it was predicted that stars close to the sun should be visible to an observer using a suitable technique. Only recently, however, has such a technique been developed, primarily for investigating the solar corona without waiting for a total eclipse. News has now reached Great Britain that a Swiss attempt to photograph stars in daylight with the aid of a coronagraph has been successful (M. Waldmeier, *Z. Astrophys.*, 21, 269 ; 1942). A photograph obtained at Arosa, at an altitude of 2,050 m. in the Alps, shows Regulus (mag. 1·34) quite clearly at a distance of 12′ (less than the sun's angular radius) from the edge of the solar disk. The observation is possible only by eliminating so far as possible diffracted and diffused light in the apparatus, and by observing at a great altitude to avoid meteorological scattering. The successful photograph was obtained at midday on August 22, 1941, with a 15-sec. exposure through a red filter. Regulus is the only first-magnitude star within 1° of the ecliptic, but there are a number of fainter stars (down to third magnitude) which, it is considered, could be photographed in favourable conditions.

One obvious application of the method is to the measurement of the gravitational deflexion of light. The Einstein effect has been observed at several eclipses since 1919 at considerable expense and with many disappointments, and the results have not been all that could be desired. The coronagraph method, if it can be developed so that precision measurements are possible (at present the objective is an uncorrected single lens, though the field which must be covered is at least 1° in diameter), will have many advantages. Accidental errors could be considerably reduced by multiplication of observations, for example, and the photographs would be taken under favourable working conditions at an established observatory instead of in the somewhat hectic circumstances of a total eclipse.

Health of New Zealand

In his annual report for 1941–42, Dr. M. H. Watt, the director-general of health of New Zealand, states that during this period cerebrospinal fever has become epidemic on a small scale, as is shown by the fact that in the whole country there were 163 cases with 25 deaths among 1,538,620 Europeans, while there were 47 deaths among about 87,000 Maoris. It was found that the meningococcus was widespread among the employees at a freezing company, which suggested that the effect of the intense cold on the nasal mucou membrane lowered the local resistance so as to allo penetration of the organism. Of recent years ther has been a considerable increase in known syphili throughout New Zealand, the number of cases treate at the clinics being 156, 192, 285 and 403 during th last four years. There has also been a sharp rise i notification of males suffering from tuberculosis similar to that found in all the Allied countries an attributable to the special methods employed in th examination of recruits. As regards vital statistics the birth-rate in Europeans was 22·81 and the death rate 9·81, while in Maoris these rates were 44·77 an 20·59 respectively. The infant mortality of th Maoris was 125·06 as compared with the Europea rate of 29·74.

Sudden Rise in Birth-Rate in the United States

According to an editorial in the January issue o the *Statistical Bulletin*, the organ of the Metropolita Life Insurance Company of New York, fairly complete data for 1942 for five large cities in the Unite States, namely, New York, Boston, Baltimore Washington, D.C., and New Orleans, show no only that the general level of births for 1942 i materially higher but also that the profile of th curve is completely changed. Instead of a sprin and a summer maximum there was a strong upwar movement of births beginning about September an continuing almost unbroken to the end of the year Moreover the level for the entire year is far abov that of the period 1938–1939. The sudden increas in births in September and October 1942 would seem to be connected with the outbreak of war in Decembe of the previous year.

Recent Earthquakes

The United States Coast and Geodetic Survey, i co-operation with Science Service and the Jesui Seismological Association, has determined the epicentres of three recent earthquakes. The first occurre on March 7 at 3h. 01·5m. U.T. from an epicentr situated 57° N. lat., 164° E. long. This is in th Pacific Ocean near the east coast of central Kamchatka Peninsula. The second and third were bot on March 9, at 3h. 25m. 32s. and 9h. 48m. 37s. U.T respectively. The first on March 9 was from latitud 42·2° N., longitude 80·9° W., which is in the bed o Lake Erie to the west of Erie (city) and north-north east of the city of Cleveland, and the second o March 9 from an epicentre at latitude 56° S., longitud 22° W., which is in the south Atlantic east of th island of South Georgia. All interpretations an calculations are tentative.

Announcements

At the recent annual meeting of the Genetica Society the following officers were elected : *President* Dr. C. D. Darlington ; *Vice-Presidents*, Dr. R. N Salaman, Prof. T. J. Jenkin, Prof. R. A. Fisher *Treasurer*, Miss E. R. Saunders ; *Secretaries*, M E. B. Ford, University Museum, Oxford ; Mr W. J. C. Lawrence, John Innes Horticultura Institution, Merton, S.W.19.

Erratum.—In the News and Views "Announcements" in Nature of July 10, we regret that w announced Dr. R. R. Mimms as being appointe lecturer in physics in the University of Birmingha This is incorrect ; for Dr. R. R. Mimms read D R. R. Nimmo.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Research and Ships' Antifouling Paints

A sub-committee of the Iron and Steel Institute recently produced the first report of the Marine Corrosion Sub-Committee. This was anticipated by the presentation of two papers dealing with the same subject. One was by Dr. G. D. Bengough and Mr. W. G. Shepheard in London, at the Institute of Naval Architects, on April 15, 1943, and the following day a very similar paper by Dr. Bengough in Newcastle-upon-Tyne at the North East Coast Institution of Engineers and Shipbuilders. These papers dealt with he work of the sub-committee carried out by the official investigator, Dr. J. C. Hudson, under the chairmanship of Dr. Bengough.

It is not proposed here to criticize technically the points of difference which research workers in the industry have with the findings of the Committee, as his has been dealt with fully in written communications to the societies at which the papers were presented. What I wish to set forth here is that the whole attitude of this new sub-committee, and the reasons for its being created, seem to have been based on the assumption that no serious research work had been done on this subject; this is very far from being true.

The suggestion underlying both the papers and the report is that manufacturers have no idea how their products function, and shipowners do not receive compositions best suited to their purpose. This is quite contrary to fact, as indeed many members of the antifouling paint industry have carried out intensive research over many years, but, of course, have not published their results, as these would be of benefit to competing firms both in Great Britain and abroad. In the early days of the industry, researches were mainly by trial and error, but it must not be overlooked that these methods resulted in quite good antifouling paints. About twenty-five years ago, to my knowledge, this method of approach had reached its limitations, and research work on strictly scientific lines by scientific men appointed for this purpose, and in no way responsible for production, was instituted. This necessitated fundamental biological work into the life-histories, methods of attachment, and reactions of marine organisms to poisonous and non-poisonous surfaces. Alongside he biological work, research in the laboratory for new and better toxins had been continuous. One new toxin, fully tried and proved, has been used in antifoulings now for twelve years or more.

In view of the above facts, it is surprising that public money and effort by scientific men is used in an endeavour to undertake work which has already been done. No one will question the importance of preventing fouling, and so maintaining maximum peed, or conversely minimum fuel consumption, in peaceful times; and under war conditions it assumes a vastly greater importance. Nevertheless, the fact does remain that the industry is capable of supplying compositions which provide longer periods of immunity from fouling than those in general use, or even those used by the Admiralty, so the work of he Committee is redundant. There are, no doubt, easons which influence shipowners not to choose the most efficient available paint, and they are presumably satisfied with what they use, which shows, at any rate, that the industry is ahead of shipping requirements, entirely due to the composition manufacturers' scientific research. It shows also that the work on antifoulings as so far carried out by the Marine Corrosion Sub-Committee is quite unnecessary; on the other hand, research of a purely academic character would be welcomed by scientific workers in the industry.

Although research work by the industry had not been published, nevertheless before the formation of this Sub-Committee, Dr. Hudson, the official investigator, was commissioned by the Admiralty to carry out investigation on existing commercial brands of antifouling compositions, and some six gentlemen, including Dr. Bengough, the chairman, and Dr. Hudson, visited the marine biological testing station of the research department of my Company, where much of the work was gone into in detail. It was assumed that this work for the Admiralty would be confidential, and there was no hesitation on our part in revealing details of that research work. That the Sub-Committee in its report makes no mention of this, and that the greater portion of the report is derogatory to the research done by the industry, is, to say the least of it, somewhat surprising.

There is one final point that I would like to mention—namely, that this industry is primarily British. Those manufacturers of antifouling compositions in foreign countries are, almost without exception, offshoots of some British parent company. The avowed intention of the Marine Corrosion Sub-Committee is to publish details of formulation and manufacture of antifouling compositions which will ultimately, of course, be available to anyone in the world. The effect on British export of such an action as they contemplate is self-evident, and does not need emphasizing.

P. Ewart Bowles.
(Director of Research.)

The International Paint and
Compositions Co., Ltd.,
Grosvenor Gardens House,
London, S.W.1.

Referring to the above letter by Dr. Bowles, I should like to make the following comments.

No statement or assumption has been made by the Marine Corrosion Sub-Committee "that no serious research work had been done on this subject". The Sub-Committee has no detailed knowledge of the amount of work done, the technique or the conclusions achieved by Dr. Bowles and his colleagues, because their researches have not been published and are not accessible to the Sub-Committee, and, therefore, no references can be made to the work. The Sub-Committee believes that, however much has been done, still more is required, partly because the fouling of both naval and merchant vessels is still a serious matter, and partly because of the wide variation in performance of compositions at present on the market made by different manufacturers, and the lack of unprejudiced guidance about their relative values in the different types of conditions to be met on the world's shipping routes.

In support of the first of these statements, I may point out that the Admiralty authorities calculate from their own practical experience[1] that 20 per cent of the total fuel burnt on warships is used in overcoming the retardation set up by fouling organisms;

for the merchant navy it is only necessary to pay a few visits to shipping home in dry-dock from certain world-routes to see that the problem of fouling has not, so far, been solved.

The statement that the anti-fouling composition industry "is capable of supplying compositions which provide longer periods of immunity from fouling than those in general use, or even those used by the Admiralty", but that shipowners do not choose to use them, suggests that the industry has failed to bring its products adequately to the notice of the Admiralty and shipowners, or that these bodies do not take the same favourable view of these products as do the makers, or that the prices charged are not reasonable. Inquiries among merchant shipping companies, particularly those trading to tropical ports, show that improved anti-fouling compositions would receive a ready welcome, provided that they enabled ships to make an additional voyage without docking, and particularly if the paints could be bought to specification and could be produced free of that expensive and scarce ingredient mercury.

The Sub-Committee's work is not a specifically war-time measure; for a country such as Great Britain, which will always be dependent on water-borne transport to bring many of its supplies, and which will still maintain a fleet, the production of the best possible anti-corrosion and anti-fouling paints will always be an important matter. This problem should, therefore, be considered from the point of view of the national interest. In his last paragraph, Dr. Bowles suggests that any successful work achieved by the Sub-Committee would interfere with the export trade of the anti-fouling composition industry, which had almost a monopoly of the export trade in pre-war days. Dr. Bowles should be aware of the immense amount of research work, both in the laboratory and on ships, which is now being done in the United States, which possesses a larger official investigating organization than that of this Sub-Committee. Much work is also being done in Japan, and, presumably, in Germany. All these countries will compete for the export trade in the post-war world, and it is certain that the United States will be in a position to produce paints of first-class quality. In Britain there is no Ships Compositions Research Organisation within which the different firms exchange and develop ideas; each separate firm carries on its own work secretly and must attempt to defend its own position individually. Similar attempts have been made by other firms in other industries, and the result has always been the same—the policy of secrecy has had to be abandoned.

The Sub-Committee is, and always has been, ready to co-operate with the anti-fouling composition industry as a whole on the basis of the free exchange of information; it invited about twenty-five firms to send representatives to a meeting, held at Cambridge in January of this year, at which many university scientific men were present; the Sub-Committee outlined its views on many topics and definitely invited co-operation, but so far no response has been received.

As regards the last paragraph but one of Dr. Bowles' letter, the facts are as follows: On December 7, 1939, a meeting of the Admiralty Corrosion Committee was held at Devonport. The chairman, official investigator and one other member of the Marine Corrosion Sub-Committee attended this meeting by invitation, and on the following day accompanied the Admiralty representatives on a visit to the Biological Research Station at Newton Ferrars, by kind invitation of Dr. Bowles' Company, to whom the Station belonged. Dr. Bowles now says that much of the work being carried on was gone into in detai and that this work was regarded as confidential; in the next sentence he complains that no mention of it is made in the Committee's report. My own recollection of the matter, three and a half years after the event, is that most of the time was taken up with a visit to the rafts anchored in the estuary for the purpose of testing paints, and an inspection of some of those paints after they had been lifted from the water. No disclosure was made as to the formulation of the paints, and no advantage was taken by the Sub-Committee of any details divulged about the rafts themselves, as decisions had already been taken about the arrangements of the Sub-Committee's own rafts. It is a little difficult to see what information Dr. Bowles expected the report to contain about this visit, which took place more than three years before its publication.

G. D. BENGOUGH.
(Chairman, Marine Corrosion
Sub-Committee.)

Iron and Steel Institute,
4 Grosvenor Gardens,

Stripe Smut of Rye

AN increasing number of farmers now make a routine practice of dressing seed corn before sowing with a reliable organo-mercury seed dressing, for by this means the following diseases are prevented bunt of wheat (*Tilletia caries*), covered smut o barley (*Ustilago Hordei*), leaf stripe of barley (*Helminthosporium gramineum*), net blotch of barley (*Helminthosporium teres*), covered smut of oat (*Ustilago Kolleri*), loose smut of oats (*Ustilag Avenæ*), and leaf spot (or stripe) of oats (*Helminthosporium Avenæ*).

Although wheat, barley and oats are so treated the majority of farmers do not appreciate the importance of using a similar dressing for their rye seed, and the manufacturers of these dressings although they recommend such a treatment, do no always specify a valid reason for its use.

It is of interest, therefore, to record that in Norfolk we have recently encountered cases of stripe smut of rye (*Urocystis occulta*), and on one farm som eighty acres were moderately affected. The disease is rare in Great Britain, for in the past twenty year the senior writer has not observed it in East Anglia, but there is a record of its appearance at Rothamsted in 1932, and Mr. W. C. Moore informs us that a small amount was found near Romsey, Hants, in May 1920, and at Askham Bryan, Yorks, in Augus 1936, on the rachis of one head in experimental plots. The disease is seed-borne and is known to be amenable to the same treatment as for bunt in wheat it can, however, be contracted from the soil. As th acreage now under rye has increased, it is suggeste that plant pathologists would be well advised t advocate the treatment of rye seed before sowing as a preventive measure against this (and other) disease and, where cases are encountered, to dissuade farmer from taking another rye crop in succession o the same field. We are indebted to Mr. R. Line for first bringing this disease to their notice.

Sharp Eyespot of Wheat caused by *Corticium (Rhizoctonia) Solani*

Eyespot of wheat caused by *Cercosporella herpotrichoides* is widespread in East Anglia, where it causes considerable loss in yield[1]. Typical symptoms of the disease are oval brown-bordered lesions on the straws near soil level. Similar, but less regular, lesions caused by another fungus have been recognized at Rothamsted as a different disease since 1935. This was described in Holland and figured by Oort[2], who called it sharp eyespot but did not identify the causal organism. Sprague[3,4] found a Rhizoctonia causing similar symptoms on wheat in Oregon. Blair[5], working with *Rhizoctonia Solani*, found that some Canadian strains when inoculated into wheat caused a stem girdling injury the photographs of which resemble those of sharp eyespot. Neither worker identified the lesions caused by Rhizoctonia as the sharp eyespot described by Oort.

We have obtained wheat plants with sharp eyespot resembling those figured by Oort, Sprague and Blair from many localities in England and Wales, and have consistently isolated from them a fungus of the Rhizoctonia type. We have inoculated wheat seedlings with six isolates from four districts; all produced sharp eyespot lesions, from which we re-isolated the fungus. The six isolates have now been identified by Dr. Bisby, Imperial Bureau of Mycology, as strains of *Corticium (Rhizoctonia) Solani*.

The symptoms of sharp eyespot are rather like those of true eyespot, and care must be taken to distinguish between them. Sharp eyespot lesions tend to be more superficial than those of eyespot and are sometimes confined to the outer sheaths, though they may penetrate the straw; they often run up the stem to a height of several inches. Sharp eyespot has asymmetric lesions with sharply defined borders surrounding pale areas on which develop spreading patches of mycelium. This is at first light-coloured but later darkens to brown or purple. True eyespot differs in having regular oval lesions, generally within two inches of soil level; they have less sharply defined borders, with black spots of mycelium concentrated in the middle of the lesions.

Although sharp eyespot has been found in many wheat fields in England and Wales and one heavily infected crop has been reported, it is seldom present in more than about 1 per cent of the straws. It does not increase with the frequency of wheat or barley in the rotations as does eyespot, which may infect as many as 80–90 per cent of the straws where wheat and barley have been grown often. In the first wheat crop after grass, eyespot is generally absent or rare, but sharp eyespot is found just as commonly as on old arable land.

Petal-Colour Inheritance in Lychnis

Investigations of petal-colour inheritance in Lychnis species have resulted in considerable confusion owing to insufficiently precise identification of the forms studied.

Numerous authors, from Bartram[1] (1699–1777) to Winge[2], have found the production of petal-anthocyanin to be dominant in crosses between the closely related *L. alba* Mill. (*L. vespertina* Sibth.), with white petals, and *L. dioica* L. em Mill., with reddish-purple petals (Shull reunites both under the latter name). By crossings in reciprocal directions I have fully confirmed this. In a back-cross between the F_1 and *L. alba*, segregation took place in the ratio of one plant with coloured petals to one with white petals.

Only Shull[3] differs from this belief, postulating that the production of colour depends upon the action of two dominant genes, each of which can be carried latent in white-petalled individuals. No other author has confirmed this and so far as I am aware Shull has not repeated it.

The existence in Nature of individuals resembling *L. alba* but possessing coloured petals (*L. alba* var. *colorata* Lange) might be advanced as support for Shull's theory, but several authors have noticed that these individuals are absent from areas from which *L. dioica* is also absent. Post[4] does not mention them from Palestine and Sinaii, where *L. dioica* does not occur. I have investigated many individuals of this kind (in several cases in swarms) and circumstantial evidence from the localities, together with positive evidence from pollen-sterility counts, measurement of certain vegetative and floral parts and comparison with hybrids (raised in the experimental plot from artificial crosses) as well as herbarium material has convinced me that they are either hybrids between *L. alba* and *L. dioica* or descendants therefrom.

In both *L. alba* and *L. dioica* the production of anthocyanin in the vegetative epidermis and the calyx (especially of staminate plants) is marked. Experiment has shown that it may be caused to develop even further by increased insolation, waterlogging of the soil, etc. Such increase is reflected in greater depth of petal coloration in *L. dioica* as the plants are transferred from shade to full exposure and vice-versa.

Although the petal-colour of the F_1 hybrid is less intense than that of *L. dioica* when the progeny is grown under the same conditions as the parent, variation of these may upset its manifestation. The matter is further complicated by the accompaniment of anthoxanthin, which certainly acts as a co-pigment to the anthocyanin, causing a blueing of the reddish-purple colour of *L. dioica*. It is present to a greater extent in *L. alba* than *L. dioica*, as might be expected on the basis of Lawrence and Scott-Moncrieff's[5] theory of the common precursor and balance of anthocyanin and anthoxanthin. These factors are probably partly responsible for the great range of colour shown by F_2 generations.

After frost or rain and as the season progresses, the shade of the coloured petals becomes increasingly blue. These facts probably dispose of Shull's factors for "reddish-purple" and "bluish-purple".

A variety of *L. dioica* is known (*L.d.* var. *albiflora* Tin.) with white petals. Examination of this form from several sources, combined with herbarium investigations at the Royal Botanic Gardens (Kew), the University of Cambridge, the British Museum

(Natural History) and the South London Botanical Institute (to the authorities of which I am very grateful) have shown that this variety contains no anthocyanin anywhere in the plant under normal conditions. My measurements show that the specimens are not hybrid segregates with white petals, although they have occurred in widely separated localities where natural hybridization has been present. It is possible that this process has been a stimulus to mutation.

A cross has been made by pollinating this form with pollen from normal *L. dioica*, which gave equal numbers of plants with anthocyanin in both vegetative portions and petals and plants containing no anthocyanin whatever. This may be explained by the assumption that inhibition of anthocyanin production is due to the action of a dominant gene, and that the white-petalled parent was heterozygous in this respect (as would be expected in a plant from Nature). The inhibition causes the production of white petals, even though the plant may carry the gene which produces petal colour, in the absence of the dominant modifying gene. The inhibition is not quite complete, for the partially unfolded petals have a faint salmon-pink colour, which reappears as the petals fade. When fully open the petals have a tantalizing "near-pinkness". The petals of *L. alba* often develop colour on fading, but this is blotchy and bluish.

The growth of a plant of the var. *albiflora* in artificially water-logged soil in full insolation has shown that anthocyanin is produced in the stem, but in very much less quantity than in normal *L. dioica* under similar conditions. Modification of inhibition is probably the cause of the pink petals developed by Harrison's[6] white-petalled variety after infestation with *Contarinia steinii*.

The presence of an analogous form in *L. alba* might be expected, and it is believed that it has been found in a group of four individuals found among many thousands of specimens growing in a field going fallow at Varndean, Brighton. That four individuals should occur so close together in a position where it is unlikely that more than two generations were present makes it probable that the inhibiting action is again due to a dominant gene. Flowers of this variety of *L. alba* do not show any blotches of colour when they fade.

The inhibition of anthocyanin production does not inhibit the production of anthoxanthin, the varieties described giving anthoxanthin reactions in approximately the same strength as *L. dioica* and *L. alba* respectively.

Lychnis coronaria normally possesses anthocyanin in both stem and petals, but a recessive white-petalled variety exists in cultivation which has anthocyanin in the stem in comparable quantity. This case is analogous with that of *L. alba*.

Further extensive pollinations have been performed, and with the results from these it is proposed to deal with the matter in detail elsewhere.

A Suggestion respecting the Bacteriostatic Metabolic Products of Moulds

IN view of the variability of many fungi and the possibility that moulds and bacteria may be mutually biologically antagonistic when growing in the same medium, it is perhaps not too fanciful to suppose that repeated culture of a mould and pathogenic bacteria together may develop increased production of bacteriostatic metabolic products of the former. Various forms of the assumed antagonism can be imagined, and competition for a common growth-factor is probably the simplest. Furthermore, provided such antagonism exists, it is easy to see that in still or viscous media the mycelial nuclei that contained cells producing the bacteriostatic substance would have the greater survival value.

I have no present opportunity to test this idea myself, but think it would be worth while to try to produce bacteriostatic substances against selected pathogens by repeated mixed cultures, using a variety of moulds for the purpose.

Sex Ratio Affected by Host Plant

THE cacao thrips *Selenothrips rubrocinctus* (Giard) is an important pest of cacao (*Theobroma cacao*) in the West Indies, West Africa and Brazil, and also attacks a number of other tropical plants, including mango, avocado, guava and cashew. It is a parthenogenetic species, although males occur rarely in the field. The males are very active and frequent copulation occurs, the sexes remaining *in copula* for from one to three minutes.

Urich[1] in Trinidad was the first to make observations on the male. Reyne[2] in Surinam found that the generation produced by mated females differed in no way from the normal parthenogenetic generation. Mating is apparently unsuccessful, and I have similarly been unable to obtain a sexual generation. I agree with Reyne's suggestion that the occurrence of males is apparently no longer of any importance to the species and is probably only a remnant of the former method of sexual reproduction. Reyne (*loc. cit.*) made counts in Surinam of 77 males and 29,100 females on cacao, the sex ratio being 1 male : 378 females and the percentage of males 0·26.

Large numbers of cacao thrips are required for experimental work in Trinidad, and they can be more readily obtained from cashew (*Anacardium occidentale*) than from cacao. The species of thrips occurring on cashew is undoubtedly the same as that found on cacao, but larger populations are as a rule encountered on the former host plant.

It was frequently observed in the field that male cacao thrips were more numerous on cashew than on cacao. Counts made in Trinidad in 1941 and 1942 gave the following results: on cacao 14 males and 9,728 females, the sex ratio being 1 male : 695 females and the percentage of males 0·14; on cashew 80 males and 3,440 females, the sex ratio being 1 male :

43 females and the percentage of males 2·33. Males were therefore more than sixteen times as numerous on cashew as on cacao.

The following, among other suggestions, might be put forward to explain these facts: (1) the production of a greater proportion of males with higher population densities; (2) the differential mortality of the sexes on the two host plants; (3) the physiological effect of the food; (4) the existence of distinct biological races on the two host plants; and (5) cashew, being supposedly more nearly allied to the original host plant than is cacao, supports a population more closely akin to the bisexual gamogenetic form hypothetically present on the ruderal host plant.

The significance of this phenomenon is unknown and no explanation is advanced. It would be interesting to know of any other examples among insects of the sex ratio being similarly affected by the host plant.

Reductone and Vitamin C

DR. F. WOKES and his colleagues have referred[1] to the chemical similarity of the reductones to vitamin C. The production of reductones by heating carbohydrates with alkali[2] is incorrectly attributed by them to Norrish and Griffiths, but it may be mentioned that the latter[3] obtained a high yield of reductone (hydroxypyruvic aldehyde) by irradiating glyoxal vapour with violet and near ultra-violet light.

Hydroxypyruvic aldehyde, a substance chemically akin to vitamin C and the carbohydrates, can be produced from inorganic sources by the following sequence of reactions:

$$(1)\ O_2 \xrightarrow[\text{light}]{\text{U.V.}} O_3;\ (2)\ O_3 + C_2H_2 + H_2O \rightarrow C_2H_2O_2 + HCO_2H;^{4}$$

$$(3)\ C_2H_2O_2 \xrightarrow[\text{light}]{\text{U.V.}} CO + CH_2OH.CO.CHO.$$

Such a short series of formally simple reactions may suggest the possibility that traces of reductone might be formed from the gases in the atmosphere without the intervention of a living organism, but this appears highly speculative.

Conception of the Tail in the Craniata

THE word 'tail' is used in the anatomy of the Craniata indiscriminately for two concepts: first, for the post-anal appendage, and secondly (especially in osteology) for the post-sacral region. While directing research on the anatomy of the Testudinata and other reptiles for many years past, I have often been struck by the unjustifiability and ambiguity of this usage and the confusion that results from it. Although in many vertebrates the two regions commonly denoted by the term 'tail' may appear to be more or less co-extensive, careful observation reveals that they scarcely ever correspond with each other to such an extent as to be regarded as identical. The anus seldom if ever lies precisely at the hinder level of the sacrum. In some cases (testudinates, crocodilians, etc.) it is a longitudinal slit and may extend beyond the limits of a single vertebral segment, its anterior rim usually lying distinctly posterior to the hind face of the sacral (or the last sacral) vertebra.

In the testudinates, perhaps, the condition is the most remarkable. While the sacro-iliac articulation lies craniad to the posterior border of the carapace considerably within the corselet, the anus occupies a position always outside the shell when the 'tail' is fully extended. Such a position of the anus, markedly posterior to the hind face of the sacrum, is apparently correlated with the functional necessity of discharging the fæces beyond the corselet margin. Thus the two regions commonly connoted by the word 'tail' are here very distinct, as the intermediate region between the sacro-iliac articulation and the anus is fully developed. The post-sacral part is always present although the post-anal region may be more or less atrophied in certain cases.

In view of this disparity in meaning, it may be best to restrict the word 'tail' uniformly to one concept, the post-anal appendage, and apply another word to the post-sacral region. For the latter a suitable term is already available, the 'coccyx' or 'coccygeal region', but its connotation has to be extended from the post-sacral region of the vertebral column to that of the body and it has to be scrupulously adopted to the exclusion of the word 'tail' whenever this region is meant. Thus the so-called 'caudal' vertebræ should be called the coccygeal vertebræ, the 'urostyle' (Gk. *oura*, tail; *stylos*, pillar) the os coccyx, and the loosely designated 'tail' of testudinates the coccyx or coccygeal region. The part of the coccyx between the sacrum and the anus, which is well developed in turtles, may be called the preano-coccyx in order to distinguish it from the post-anal part of the coccygeal region (postano-coccyx), which is equivalent to the tail, *sensu strictu*.

If we accept this nomenclature, the cyclostomes and fishes have a tail, but no coccyx differentiated at all, as the sacro-iliac articulation is lacking. In other words, they form a division of the Craniata which may be called Acoccygea. The coccyx is distinguished only when the sacro-iliac articulation makes its appearance, and this happens in the Tetrapoda, which may, therefore, be designated Coccygeata.

Among the Coccygeata, the amphibians and reptiles, as a rule, have the tail and the coccyx well differentiated, more or less corresponding with each other but never co-extensive. The difference in position between the anus and the sacro-iliac articulation, which is responsible for the variation in extent of these regions, is explicable on the basis of functional requirements, since the position of the vent always corresponds to the place behind the sacrum where the muscular movements connected with the pelvic musculature on one hand, and the caudal on the other, bound an area of little myogenic disturbance. This is essential, as otherwise the violent movements of the adjacent muscles might disturb proper defæcation.

In snakes the sacrum has been secondarily lost and thus the coccygeal region is not distinguished from the preceding part, although the tail is well defined.

In the Testudinata, the preano-coccyx contains an extension of the cœlom around the terminal part of the gut, a feature which is always absent in the tail, strictly defined.

Extant birds have a small coccygeal prolongation but no true tail, although some extinct forms (Archæopteryx, for example) had a fairly long tail. Mammals have both.

Developmentally, the vent, as is well known, marks the position of the blastopore, so that a true tail is strictly post-blastoporal in origin.

Arapesh Maternity

The Arapesh are a people of an area of north-western New Guinea lying at and about 143° 30′ E., and 3° 30′ S. They have a custom of segregating women in outshelters at all times of the catamenia. Like most other women in this respect, Arapesh women do not ovulate or menstruate for an interval after parturition and during nursing. This organic quiescent period is usually known as the lactogenic interval. The Arapesh have the unusual custom that a woman and her husband must notice the advent of the first post-partum onset of menstruation in her body by giving a feast to the neighbours. The first post-partum onset of menstruation in a woman's body during lactation is termed in the Arapesh tongue *helib*. The feast given by a woman and her husband to the neighbours a few days after *helib* is termed in Arapesh *Kwa di batauin*. It takes place, on Arapesh evidence, between six to twenty-five months after child-births, as noted by the nursling having first cut its first two incisors (6–9 months) in some cases, and having first cut all its milk teeth (24 months) in other cases, with a modal time about the intermediate age of the nursling walking and talking.

There are said to be no Arapesh women who resume menstruation during nursing before the infant has cut its first incisors, although the clinical evidence indicates that some Caucasian women resume menstruation during nursing as early as one month after the birth of the child[1]. The Arapesh are an inbred group not more than eight thousand in number, and they may all be representative of a constitutional type with a comparatively long lactogenic interval. However, there is no known explanation of this point of difference. There are said to be some Arapesh women who do not resume menstruation during nursing until the infant has first cut all its milk teeth. The clinical evidence does not indicate that any Caucasian women have as long a lactogenic interval as this. However, the maximal time of the interval, stated to be not long over twenty-four months in the Arapesh population, is possibly not matched in the data available on the Caucasian population, because Caucasian populations usually wean infants before that time, and because early weaning may bring a lactogenic interval not already closed to a close. It may be noted that nursing for three years, which is common Arapesh practice, does not prolong a lactogenic interval for three years.

An assumption in respect to the conditions of a particular type of co-ordination of vital processes is not in the same field as a proof of the action of isolates or of near isolates in vital activities. The assumption that instances of a twenty-four months long lactogenic interval depend upon nursing being continued at least as long, and upon an individual constitutional factor, is not, for example, in the same field as a proof that a certain fraction, not isolated, obtained from the pituitary gland can initiate mammary secretion, and, in some species, stop ovulation[2]. Nevertheless, the assumption is reasonable.

The observation that nursing for three years will not prolong a lactogenic interval for three years is good against the chance, however remote or however proximate it may be, that prior resumption of sex relations after parturition may be an interfering factor provocative of renewed ovulation. The Arapesh do not resume familial sex relations after parturition until after *helib*.

The idea behind the Arapesh practices discussed here is evidently an idea of controlling population growth by abstinence during the lactogenic interval, adjusted to the exact length of time of the interval in individual cases. In previous accounts of Arapesh sociology[3] the idea in point has been distorted and the associated practices incorrectly described. The social 'culture' has been described as "working, selecting a maternal type as desirable, and embodying this choice in every thread of the social fabric"[4]. The Arapesh have, in fact, a predilection for maternal types. They believe, not without prejudice to some, that the constitutional types with the longest lactogenic interval make the best mothers. Nevertheless in matters of history and of social 'culture' the Arapesh still embody ideas in their social fabric. They do not attempt the impossible task, attributed to them, of embodying one constitutional type rather than another, instead of ideas there.

In an account of the associated practices the ceremonial feast at *helib*, namely, *Kwa di batauin*, has been omitted, and the resumption of familial sex relations after parturition has been dated about the time of the nursling walking and talking, without reference to the point that it occurs, in fact, at various times, but always a few days after *helib*.

AGRICULTURAL EDUCATION ASSOCIATION

SUMMER CONFERENCE

AT the summer conference of the Agricultural Education Association held at the University of Reading on July 8 and 9, the chief topic for discussion was the Report of the Luxmoore Committee on Post-War Agricultural Education. Lord Justice Luxmoore himself was to have been the guest of honour at the conference dinner on Thursday evening, but was prevented from attending by ill-health. Mr. W. J. Cumber, who proposed the toast of the Agricultural Education Association in Lord Justice Luxmoore's place, said that science has yet a lot to teach the agriculturalist, and he himself, in going to the institutes, colleges and universities with the Committee, had learned a great many things which were going to be of advantage to him. He believed in mixing up science with practice, for in that way only would it be possible for British agriculture to compete with the rest of the world.

Three sessions were devoted to discussing the Luxmoore Report, and to facilitate the deliberations a memorandum had been circulated to members asking specific questions. The first question, for example, was: Does the Association agree that *compulsory* continuation classes should be under the Board of Education ? With practically no discussion, members agreed.

The second point was, Should the national authority for voluntary agricultural education be a New National Council; the Ministry of Agriculture with appropriate technical staff; or the Board of Education ? There was some difference of opinion on these alternatives, though the last authority did not find a supporter. Regret was expressed that the Committee, in considering the re-organization of agricultural education, had not studied the system operating for many years in the United States. Some members thought that the relationship between the Minister of Agriculture and the proposed new national council had not been made sufficiently clear, while others feared that the report envisaged a system of autocratic, centrally-governed education. Others, however, felt that under the proposed central council some of the financial difficulties of the poorer counties might be solved, while at the same time the agricultural education service as a whole would be given a professional status. Eventually it was unanimously agreed that it should be the statutory duty of a competent central body to ensure that adequate agricultural education is provided throughout Great Britain; by a five to one majority, the proposed new National Council was approved as the national authority for voluntary agricultural education.

There was an interesting debate about the desirability of local advisory committees having executive powers, the general feeling being that it would not be possible to get together or hold together the best men on committees that are purely advisory. The desirability of each county initiating the scheme of education best suited to it, rather than having a central scheme forced upon it, was also stressed, and the meeting passed a resolution that the National Council should work through new committees with executive powers to initiate and carry out approved schemes of agricultural education.

With regard to the specialist advisory service, it was suggested that certain of the science subjects, such as mycology and entomology, are not of sufficient economic importance to justify specialist advisers, and that there should be provision for advisory officers in the broader subjects such as botany, grassland, animal husbandry and plant husbandry. American experience was quoted on this matter, and after further debate it was agreed that the present classification by sciences is unsatisfactory and inadequate, and that attention be directed to the need for re-grouping in order to cover the whole field of agriculture.

The conference was unanimous in deploring the proposed separation of the teaching and advisory services, which would seriously impair the efficiency and usefulness of both, and it did not agree with the drastic reduction in the number of provinces recommended in the Luxmoore Report. It also concluded that the unification of the advisory work of the county organizer and that of the specialist provincial advisers would not be easily secured under a provincial administrator, and it re-affirmed the principle laid down in the evidence submitted by the Association to the Luxmoore Committee, namely, that "it is the opinion of the Association that for the efficiency of advisory work all local organizers and specialist advisory officers should be members of one organisation, but this opinion is expressed without prejudice to the opinions held by members about the best administrative means of effecting such unification".

The conference then proceeded to discuss in detail the proposals of the Luxmoore Committee regarding farm institutes, agricultural colleges and university departments of agriculture, taking the paragraphs as set out in the Report. Many of these paragraphs were accepted without debate, but on others there was a useful exchange of opinions which considerations of space make it impossible to report adequately. A fuller account will appear in the Association's journal *Agricultural Progress*. It is interesting to note, however, that there was general condemnation of the national diploma in agriculture.

During the three sessions, the conference was very greatly helped by the contributions of Mr. R. Ede, secretary of the Luxmoore Committee, whose explanations and general assistance were much appreciated by members of the Association.

Turning now to the formal papers, there were two of outstanding educational interest. The first was a description of the progress of grassland research in the United States by Prof. D. B. Johnstone-Wallace, who has returned to Great Britain on special leave after fourteen years as agrostologist and professor at Cornell University. Grassland research in the United States is a comparatively recent development; Prof. Johnstone-Wallace found that there was very little work being done on pasture improvement when he made his first tours in the eastern States during 1929 and 1930. Since then, the importance of phosphorus and nitrogen have been recognized, and the high value of wild white clover has been amply demonstrated. Detailed examination of strains of herbage plants from all parts of the world have been carried out, and it has been found that Kentucky blue grass (*Poa pratensis*), creeping red fescue, and certain types of timothy and cocksfoot, together with wild white clover, are the most useful species for general use. Much is expected from bird's foot trefoil, which has been found to possess drought-resisting properties of a high order. For silage purposes a combination of Ladino clover (a giant species of white clover) and

Aberystwyth "mop" cocksfoot has given exceptionally good results.

An interesting development in the pasture work at Cornell is the detailed examination of the movements of grazing animals, during which the actions of beef cows are accurately recorded throughout complete periods of 24 hours. It had been found that a cow grazes only 8 hours daily, lies down 12 hours, 'stands about' 4 hours, and chews the cud 7 hours. It walks about 2½ miles a day, drinks water only once, and grazes to within half an inch of the ground surface. It prefers herbage that is four to five inches long, and if the grass grows longer than this its consumption falls off. Altogether, this piece of research provides a remarkable confirmation of the value of rotational grazing.

The second paper dealt with the organization of agricultural education in the United States, and was given by Prof. R. Rae, of the University of Reading, who recently made a tour of the principal agricultural colleges in America. In general, the American system resembles that in Britain, for the activities of each centre fall into three main sections, teaching, experiment or research, and extension service. Prof. Rae, however, was very favourably impressed with the way in which all the various agricultural services, both State and Federal, are grouped together in the same town, and he believes that Great Britain might well give serious consideration to this point when considering post-war organization. Equipment for teaching purposes is on a much larger and more generous scale than we have ever aspired to; some of the examples quoted by Prof. Rae left no doubt in the minds of his audience on this point.

Extension work was described as "the educational arm of agriculture in the United States. It is a co-operative project between Federal, State and local governments, and private groups of farmers and people. . . . It has a large number of local unpaid volunteer leaders consisting of farmers and farmers' wives, and a relatively small paid staff". These extension services combine in America the fields of work covered in Great Britain by the advisory service and the county agricultural staff. From Prof. Rae's paper, however, one got the impression that it goes further than the British system; for example, there are more than a million volunteer neighbourhood extension leaders organized into a system whereby, the Government can reach every farm family with important information on measures necessary in connexion with the War, while "through doing, and leading others, the rural man, woman or youth who takes part in extension work experiences a change in his or her person. This change is one that builds ability and greater confidence in self and future".

PEOPLES OF NEW GUINEA

THE ninth of the Smithsonian War Background Studies series deals with New Guinea*, that fascinating island which lies to the north of Australia and has been so much in the public eye since Japan entered the War. With its central backbone of high mountains and its coastal areas of swamp or coral reef, it is an island of great contrasts, while the discovery of gold in the interior proved a notabl addition to the valuable traffic in bird of paradis plumes—now forbidden. The island is divided int three portions, the westerly administered by th Netherlands, the south-east by Australia and th north-east, formerly German, also by Australia unde a mandate. Owing to the difficulty of travel, whic was done for the most part by rivers, the interio remained only partially explored until recently when air transport to the goldfields opened up a great deal of the interior.

The natives are of three main stocks, the Negritos in the northern mountains, the Papuans and the immigrants from Melanesia; there has, naturally been a lot of inter-marrying, but the three groups are easily distinguishable. The Negritos are a small woolly-haired people found at certain spots along the central range, living still in the stone age, and with bows and arrows and a deadly stone axe as weapons They are on the whole a friendly and cheerful people and presumably the earliest human inhabitants. The Papuans, who also arrived in the island at an early date, are the characteristic racial stock and are a bigger race than the Negritos; they are dark-skinned woolly-haired and inclined to be bearded. They occupy most of the interior of the island and all the west and south-western coastal region from Geelvink bay to the Gulf of Papua, as well as other scattered areas. Although they practise a certain amount of simple cultivation, they are more typically hunting and fishing folk with a strong tendency towards cannibalism, headhunting and fighting in general. The Melanesians—the latest arrivals—are found around the east, north-east and south-east coasts and are a lighter-skinned race with hair that may be frizzy or wavy. (The author's statement that they are dark-skinned and woolly-haired does not tally with the descriptions by Seligman and other authorities.) They are a sea-going folk with fine outrigger or double canoes and are of a more cheerful disposition than the often morose Papuans.

It is a pity that some photographs of these attractive people and their culture in the south-east could not have been included in this publication, instead of the illustrations being confined to Netherlands New Guinea.

K. RISHBETH.

EDUCATION IN THE ARMY

DURING the winter of 1942-43 Dr. S. J. Curtis acted as chief instructor at the various courses of army education held at the University of Leeds. The courses were designed to be of assistance to regimental instructors who, on returning to their units, were invited to lecture and introduce discussions and in other ways promote the growth of the war-time scheme for education in the Army. As the courses proceeded it was recognized that a useful purpose would be attained by providing the instructors with information about the institution to which they owed allegiance, the British Army. Most soldiers have some knowledge of their particular regiment, but many are unfamiliar with the regiment's place in the general background of the Army. Dr. Curtis' excellent little volume[1] has been prepared to meet the deficiency. The soldiers who read it will scarcely avoid feeling a legitimate pride as members of an organization whose proud record is still unfolding. "The Story of the British Army" should find its way to every unit library and would still reward the soldier who added it to his already over-weighted haversack.

---

* Smithsonian Institution. War Background Studies, No. 9: The Native Peoples of New Guinea. By M. W. Stirling. (Publication 3726.) Pp. vi+25+28 plates. (Washington, D.C.: Smithsonian Institution, 1943.)

"Adult Education in H.M. Forces"[2] suggests that the book is mainly concerned with a description of the educational scheme which has been developed in all three Services. This is not so. It has been designed particularly for the use of regimental instructors. On the other hand, Major Phillips and Capt. Curtis are much too modest in stating that the book would be useful only for unit *education* instructors. It would be of considerable value to all men and women in H.M. Forces whose duty it is to train other men and women in the use of weapons, the principles of wireless, the precautions to take against gas attacks or any other duty which involves the use of the instructional method. This point is admirably summed up in the preface by Brigadier C. G. Maude, controller of the Army Educational Corps, in his remark that "it is now no longer enough for an instructor to 'know his stuff', he must be able to 'put it across' in a clear and interesting manner".

The introductory chapter contains a brief account of the development of education in the Army. For the instructor the well-written chapter on "How People Learn" should be of great value. Here the authors emphasize the point that the real aim of the instructor is to stimulate others to learn, and not merely to impart knowledge. This brings out the important point that instruction is an active process for both speaker and listener.

Other sections of the book deal with the manner in which a talk might be prepared, the use of visual aids and the methods of guiding discussions. One or two examples to illustrate teaching method are included as well as some useful hints on how to handle adult classes. The book will be warmly welcomed by many Service men and women who, for the first time, have been called upon to instruct others.

TESTING AND RATING AIR FILTERS

EQUIPMENT for securing data on the efficiencies of air filters is described in an article by O. C. Eliason (*Bell Lab. Rec.*, 21, No. 8; April, 1943). The laboratory test for measuring the capability of a filter consists in passing air containing a known concentration of a standard dust through the filter and measuring the amount of dust remaining in the air. The equipment includes a wind tunnel with a variable speed blower for controlling the volume of air, and there are pitot tubes and gauges for measuring the flow and the static pressure of the air in the tunnel.

A machine has been developed for feeding dust into the air stream in the tunnel at a constant rate. A chain carries the dust from a hopper and drops it into an aspirator tube, from which it is blown into the air stream of the wind tunnel. A moving arm in the hopper stirs the dust and also wipes across the chain to ensure that it carries a uniform load. A standard dust, consisting of a mixture of lamp-black, powdered charcoal, iron oxide and wood flour, was chosen after considerable experimentation. It contains those components of natural dust which are most likely to tax the ability of air filters where dust conditions are severe.

An air sampling instrument for use in the field or in the laboratory was developed as a relatively accurate and easy means of determining, by weight, the amount of dust in the atmosphere and at the same time, by a discoloration test, affording a visual indication of the amount and character of the dust. It consists of a cylindrical chamber with one end screened and provided with a pipe, equipped with a pitot tube for measuring air flow, which connects the chamber with the suction side of a blower. To obtain a sample of the dust in the air, a white filter paper is placed over the screen and air is drawn through it at a constant rate. The dust in the air is deposited on the paper and its amount is quantitatively the difference in the weight of the paper before and after the test. The visual indication is given by the discoloration of the white filter paper.

The air filter on test is installed in the end of the wind tunnel and the volume of air through it is adjusted to its rated value. The dust feeder is then started, the volume of air and the rate of dust feed being constant throughout the test. Samples for determining efficiency are taken during the first hour and at specified intervals thereafter. Efficiency of dust removal is expressed as a ratio of the dust removed compared with the dust in the air entering the filter.

From the weight of dust fed during the test and the volume of air delivered by the blower, the amount of dust in grams per cubic foot of air entering the filter can be calculated. The corresponding amount of dust in the air leaving the filter can be calculated from the weight of that collected on the filter paper and from the volume of air passed through the filter paper. The filter paper is weighed before and after test on a balance sensitive to a tenth of a milligram, in a room in which temperature and relative humidity are constant. When tests are to be made outside the laboratory on air filters installed in a ventilating system two samplers are used, one on the intake side of the filter and the other on the outlet side. The efficiency of the filter is calculated from the difference in the weight of dust collected on the two filter papers.

A NEW ORDER OF CRUSTACEA[*]

THE minute crustacean which is the subject of this paper is a very interesting discovery. *Derocheilocaris typicus* n.g., n.sp., was found on the intertidal beaches and is regarded by the authors, probably justifiably, as belonging to a new order, which they name Mystacocarida. Although obviously closely allied to the Copepoda, it differs fundamentally in certain respects and is highly specialized in some ways and very primitive in others. The body consists, as in the Copepoda, of sixteen somites, of which the last six are legless. The somite of the maxillipede (first thoracic somite) is completely separated from the head—a most unusual feature. The last six

[*] Mystacocarida. A New Order of Crustacea from Intertidal Beaches in Massachusetts and Connecticut, by Robert W. Pennak and Donald J. Zinn. (Smithsonian Miscellaneous Collection. Vol. 103. No. 9. Smithsonian Institution, Washington, Publication 3704. 1943.)

somites are regarded as abdomen, but a comparison with Gurney's[1] diagram (p. 33, Figs. 22–23) of the segmentation of a copepod shows a more likely interpretation to be that the first three are thoracic, the corresponding legs being lost altogether. Thus the body would be divided into a head of five somites, thorax of eight, and abdomen of three. The four legs present are simple and leaf-like.

The mouth parts are relatively unspecialized and apparently function in straining food particles out of interstitial water of sandy beaches. There is a large labrum. On the antenna of the larval stages is a so-called "quasi-palp" which disappears in the adult. It is suggested by the authors that this may function (or at one time did function) as a clasping organ, and in that case that the fifth larval stage may be (or may have been) a functional male phase. It seems clear, however, that this "quasi-palp" is homologous with the masticatory process of the Branchiopod larva (see Gurney[2], p. 18, Fig. 5). Five larval stages were found, but not a complete series, and there are probably still younger forms. All have two pairs of antennæ, mandibles, labrum, second maxillæ and caudal rami, only the two last having the first maxillæ and maxillipedes, although all have the so-called postcephalosome (somite of the maxillipede) already formed. No males were seen.

A very strange feature is the presence of the genital opening on the first thoracic somite. If correct, this is a fundamental peculiarity. More evidence is required, especially the tracing of the gonoduct.

It is claimed that in Derocheilocaris we have the most primitive living crustacean yet discovered. In spite of its undoubtedly primitive features, however, and its unique peculiarities, its close relationship with the Copepoda and even further specialization, particularly shown in the greater reduction of the thoracic limbs, make this supposition untenable. It is hoped that further details of this most interesting animal will soon be available.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Horticultural Officers (2)—The Executive Officer, Essex Institute of Agriculture, Writtle, Chelmsford (August 14).

Lecturer in Physics (temporary)—The Acting Secretary of University Court, The University, Glasgow (August 15).

Lecturer in Physics—The Principal, College of Technology and Commerce, Leicester (August 16).

Principal of the Queen's Royal College (Secondary School for Boys), Trinidad—The Secretary (I.P.R./C.A.), Board of Education, Belgrave Square, London, S.W.1; residents in Scotland should apply to The Secretary, Scottish Education Department (Branch Office), 29 St. Andrew Square, Edinburgh (August 16).

Assistant Lecturer and Demonstrator in the Physiology Department—The Secretary, The University, Birmingham (August 18).

Lecturer in Chemistry in the Brighton Technical College—The Education Officer, 54 Old Steine, Brighton 1 (August 18).

Laboratory Steward in the Science Department of the Doncaster Grammar School—The Chief Education Officer, Education Offices, Doncaster (August 21).

Head of the Department of Industrial Administration—The Registrar, College of Technology, Manchester 1 (August 23).

Professor of Animal Husbandry (Hygiene and Dietetics)—The Secretary, Royal (Dick) Veterinary College, Edinburgh (August 31).

Power Station Superintendent—The Engineer and Manager, Brighton Electricity Undertaking, Electric House, Castle Square, Brighton 1 (endorsed 'Power Station Superintendent') (August 31).

Deputy Director of the Research Department at Loughborough—The Secretary, Institution of Production Engineers, Portman Square, London, W.1 (endorsed 'Deputy Director Research').

Supervisor in connexion with the National Milk Testin Scheme, and a Dairy Bacteriological Assistant, in the Universit of Bristol—The Chief Advisory Officer, Agricultural Advisory Offic 22 Berkeley Square, Bristol 8.

Assistant Master to teach Science (with an Engineering bia and Practical Mathematics in the Forest of Dean Mining an Technical School and East Dean Grammar School—The Secretar County Education Office, Shire Hall, Gloucester.

Lecturer in Education, Psychology, and Social Philosophy—The Clerk to the Governors, South-West Essex Technical College an School of Art, Forest Road, Walthamstow, London, E.17.

Assistant Master in the Day Junior Technical School to teac Technical Drawing and Engineering Science; a full-tim Lecturer in the Department of Mechanical Engineering (qualifie to teach up to Higher National Certificate standard); a full-tim Lecturer in the Department of Mechanical Engineering (work training, previous teaching experience, and a suitable Degree a essential); a full-time Lecturer in the Department of Electrica Engineering (qualified to teach Electrical Engineering to Degre standard for the Higher National Certificate); and a full-tim Lecturer in the Department of Mathematics—The Principa Borough Polytechnic, Borough Road, London, S.E.1.

EDUCATIONAL RECONSTRUCTION IN EUROPE

THE picture of German efforts to suppress every kind of knowledge which is likely to conflict with totalitarian theory, and of the systematic thoroughness with which attempts have been made to standardize thought, given in the report "Axis Oppression of Education"[*] gives some measure of the immensity of the task of education, or re-education, which has to be undertaken in the enemy-occupied countries when they have been liberated. The task of re-educating Germany itself is even greater, and is one of the most difficult problems involved in the building of a new world order. The soundness of the prediction of the American historian, Charles Beard, in April 1936, that if the Hitler regime continued for several years the German people would be a people almost totally ignorant of the outside world, has been established by all that has elapsed since then.

No plan for the reconstruction of Europe which side-tracks or ignores this issue can hope to have any permanent results. The report "Education and the United Nations"[†], which was issued in March by a Joint Commission of the London International Assembly and the Council for Education in World Citizenship, should effectively dispose of any attempt to disregard this problem, though one might have looked for more attention to it in the memorandum on policy towards Germany which has since been issued by a Post-war Policy Group of members of both Houses of Parliament, of which Sir John Wardlaw-Milne is chairman. The Commission referred to above included members from twelve countries, among them China, the United States and Fighting France, and had as chairman Prof. Gilbert Murray, himself president since 1928 of the International Committee on Intellectual Co-operation.

The report falls into three principal parts. The first, which draws considerably on "Axis Oppression of Education", describes the extent and importance of the destruction inflicted by the Nazis, together with the measures recommended for restitution. The second examines the prospects and principles of re-education in Germany; and the third deals with education as a foundation for the post-war system, and the reforms and expansion necessary to secure the general raising of educational standards without which the ideals of the Atlantic Charter will end in disappointment. A campaign for a real attack on the giant of ignorance, which is an essential step in the establishment of the Four Freedoms, is outlined with conviction and with imagination.

It may be admitted that the free peoples of the world have scarcely any real conception even yet of the enormity of the destruction that has been wrought and the crimes that have been perpetrated by the Nazi armies and their imitators from Italy and Japan, and the report may well give further publicity to an aspect of the problem which was discussed in these columns earlier in the year (NATURE, February 6, p. 147). The Commission argues cogently that the work of educational reconstruction must be a combined effort of all the United Nations, and one of their first tasks when hostilities have ceased. Its specific recommendations, including the appointment now of a United Nations Bureau for Educational Reconstruction to prepare and, so far as possible, put into operation the necessary plans for meeting those needs which are too great for any one nation to bear alone, deserve the urgent and careful consideration of all the Governments concerned.

---

[*] Axis Oppression of Education. Report of the Inter-Allied Information Committee. (London: H.M. Stationery Office, 1943.) 3*d*. net.

[†] Education and the United Nations. Report of a Joint Commission of the London International Assembly and Council for Education in World Citizenship. Pp. 54. (London: Council for Education in World Citizenship, 1943.) 1*s*. net.

Unless the Nazi system is extirpated, and the traditional militarism dominant in Germany and its supporting elements are overthrown, there is no hope for a peaceful Europe. The Commission holds that the first essential condition of the re-education of Germany is that the whole Nazi organization should be destroyed, the power of the German army broken, justice meted out to the war criminals, the fullest restoration of stolen property made, and the reality of defeat manifested to all the German people, so that they learn that aggression does not pay and place upon their present leaders inescapable responsibility for the just fate that overtakes them. With this principle the Commission holds that no fundamental re-education of the German people is possible if they are placed in a position of permanent inferiority, and that the re-education of Germany and the moral and spiritual regeneration of her people are no less important than their physical disarmament.

Education is unquestionably one of the surest foundations of peace, and the Commission submits that for the advancement of education and the cultivation of a right attitude of mind in all countries, the United Nations should establish an International Organization for Education with wider representation and greater powers than the International Committee on Intellectual Co-operation. The social objectives of the Atlantic Charter can only be achieved by a general raising of educational standards. Such an advance itself must be a matter of international agreement and may involve financial assistance for some of the poorer States.

The proposals for an International Organization for Education, which should be one of the principal parts of any new international authority, are to be further detailed in a subsequent report. While, however, it is true generally that only in so far as the rising generation can be educated for world citizenship will it be possible to maintain the solidarity of the United Nations and ensure peace, before Germany can co-operate in any such enterprise the German people must first be re-educated, and there is much to support the view of the Commission that they must re-educate themselves. The conquering Powers can, it is true, do something to create the conditions in which the re-education of the mind and character of the German people is most likely to succeed, and for this purpose the Commission suggests that the Occupying Powers should exercise their control of education in Germany through a High Commissioner for Education, who should be chosen in advance an ready to start work immediately occupation begin His purpose should be to eradicate the Nazi ar militarist influences in education and to inspir facilitate and supervise measures by the Germa people for their own re-education. The occupatio should continue at least until the High Commission is satisfied that his work can be taken over by t Germans.

The report makes no attempt to conceal t difficulties of any such proposal. The High Con missioner should be assisted by a Commission draw from Allied and neutral countries, which woul conduct a thorough examination of the who educational system in Germany and recommend wh further measures should be taken to eradicate Na and militarist teaching, and provide that gener framework of education in which the ideals of t Atlantic Charter are more likely to find suppor There is no reason to assume that all teachers professors who have retained their posts under Na rule are in sympathy with Nazi ideas, and it will important to discover as many men and women possible in Germany who are willing to assist eith as teachers or in other ways. While there must no reluctance to issue orders for the removal appointment of educational authorities, the dismiss of teachers, or the suppression of certain school-boo when necessary, it is essential to foster in every wa the foundation of properly constituted German educa tional authorities and organizations of teachers wh desire to give to education in Germany a huma and international purpose.

There are many detailed proposals outlined in t report which deserve attention. Some, like t suggestion that it might be worth while for Germa exiles during the War to prepare new text-books though these would obviously require careful e amination before their adoption for use in German —could be given immediate effect. Others, such the recommendation that the High Commission should ensure the removal from the universities all who gave active support to the Nazis or racialism in any form before 1933, or who have he high office under the Nazis such as rectors or *Dozen enführer*, and of all professors of *Rassenbiologie* an such bogus sciences, must wait until the occupation Germany begins. For others again, such as t substitution of some other form of organized yout activity for the Hitler *Jugend*, which must be di banded, and the supervision of the organized leisu activities of German youth, for which the Hig Commissioner would be responsible, the constructi thinking that is the first step should be proceedi already if the tentative lines of policy and action a to be prepared in time.

Mr. R. A. Butler, in an address to the Foreig Press Association, has given some support to the views. Urging that the process of re-education mu be the recognition by the enemy that war does n pay, he pointed out that the liberation of the Germa mind could only come about by an internal proces possibly a slow process, and as a result of ove whelming military defeat. It is essential, howeve that no great nation should stay outside any international machinery set up for education or any other purpose, and as Prof. E. H. Carr has remarked, we must give the German people not only a common interest in the building of the new Europe but also the sense of a common moral purpose, and in that sense re-education of Germany is only possible if we are prepared in the course of this process to re-educate ourselves.

For this reason it is encouraging to find recognition of this truth in a thoughtful study "Relations with Europe" issued by the editors of the American periodical *Fortune*. A section of this report devoted to the special problem of Germany recognizes the critical importance of education and its control; it urges the establishment of a European Education Office among its other proposals designed to degrade the Nazi regime, to establish the individual rights of every German to life, liberty and happiness—in contrast with the serious disabilities under which the German nation must be for years. Another point made is the need for the international administration to discover and train anti-Nazi Germans who show an instinct for leadership. Mr. Butler indicated that plans were already being made to repair the devastation of the educational system of Europe caused by Nazi methods based on the rejection of truth. In collaboration with the British Council, the needs of schools and colleges which will have to be restarted in the occupied countries would be dealt with first, particularly the provision of equipment and the discovery and training of prospective teachers. This matter is, of course, also being studied by the British Association Committee on Post-War University Education (see NATURE, December 19, 1942).

In the last resort, the possibilities of re-education in Germany and the nature of that re-education depend upon issues far outside the scope of the report on "Education and the United Nations" referred to above. The absolute power of the United Nations will give them a decisive influence on the development of internal conditions in Germany, and upon the policy they pursue towards Germany will depend the possibility of there emerging a new German State, with such social and economic conditions as will enable it to provide for all its people, without distinction of class or creed, a fuller and happier life of peaceful development and service to the community than they have ever before known. We can expect the German people to re-educate themselves as good citizens of Germany and of the world community only when they have grounds to hope for such a future—and, it might be added, the refugees from Germany will participate in this work only on those conditions.

It would, indeed, be unreasonable to expect refugees to participate unconditionally, and each additional year of war may well make their contribution more difficult. There is, therefore, all the more reason for neglecting no steps which can be taken to lay the educational foundations of the post-war system. The attempt to fit men for a better society must not be delayed while we are striving to create such a society. The restoration, protection and advancement of education must be regarded as a major task in settling the affairs of the world after the War. Unless some great purpose beyond the winning of the War animates the hearts and minds of men in all the United Nations, there is grave danger that once the urgent tasks of reconstruction have been completed, all our plans for destroying the power of our enemies to wage aggressive war and for the re-education of their people may come to nought, and the world once more may drift to war.

In this section of the report there are several suggestions for the extension of educational facilities, and particularly education in the principles of world citizenship. Methods for ensuring for all teachers a period of training in which they will make closer contacts with the lives of other people and gain a wider experience of life; raising the status of teachers to that of other great professions; a new emphasis in the teaching of all subjects; further participation by the universities in the work of adult education; the fullest co-operation between learned societies; the development of the Nansen pioneer camp: these are among many suggestions too numerous to be enumerated. The Commission proposes to examine more fully at a later stage various proposals regarding the universities, but it emphasizes the desirability of students of arts and theology receiving some introduction to the elements of scientific knowledge and some training in scientific methods of thinking, and of students of natural science receiving a similar introduction to philosophy and the social sciences. It is further urged that the present need and possibility of establishing in Great Britain an international institution of university character for research and teaching in all subjects related to international affairs, and for the provision of popular extension courses in those subjects, should be fully considered by the appropriate bodies.

Among the numerous practical suggestions of this valuable report are some that might well receive immediate attention, particularly in relation to the enemy-occupied countries. The Commission has been particularly impressed, for example, by the way in which the representatives from Greece are prepared to tackle the problems of reconstruction in their own country after the War, and there appears to be no reason why investigations of the possibility of founding in Egypt or in Great Britain during the War a training college for young Greeks aspiring to return to their native land as teachers, or to arrange special courses for them, under their own instructors, at some British training college or university training department, as recommended in the report, should not now be instituted. Moreover, as the Commission indicates, serious research is likely to be possible only in Western and Northern Europe for some years to come, and it is therefore the more imperative that plans should be ready for preventing, if possible, the theft of educational and research endowments, or for speedy restoration, and for dealing with the problems which may be created by changing economic conditions.

Many of the proposals of the report, and indeed all plans for educational reconstruction, involve political questions which will require the most careful examination. The failure of the Nazi attempts at re-educating the occupied countries is a warning as to the seriousness of the political problem and difficulties, and prophecy as to how wide the response of German youth to any such attempt at re-education or how many Germans are to be found, as Mr. Henry A. Wallace suggested, steeped in the German liberal tradition and the ideals of Scandinavian co-operation, to whom the task could be entrusted, would be extremely rash.

Educational reconstruction must form the basis of our plans for final reconstruction in Europe, but it must be linked with our political policy; and the two must be determined not in isolation but with regard to their reactions one on the other. On that relation depends very largely the answer to the question "Can We Win the Peace ?" Dr. Einzig's recent book of that title*, like the memorandum of the Post-war Policy Group, makes it clear how fundamental and important are the decisions as to our attitude to Germany which must be taken before any consistent policy can be framed. The points which the latter memorandum suggests for inclusion in the peace terms, for example, cannot well be considered apart from their effect on the probable attitude of Germany to the final post-war settlement. This applies particularly to such political matters as the proposal for breaking up Germany. As a contribution to lucid thinking about the fundamental issues, Dr. Einzig's book deserves attention, unpalatable as many may find his conclusions. On one indeed there can be no disagreement: the complete and unilateral disarmament of Germany is fundamental to winning the peace, and his suggestions on German trade and production after the War are designed to supplement that disarmament by making it impossible for Germany to regain her economic hold of the Balkans and other countries, while at the same time offering her people the prospect of a high standard of living if they co-operate in the new European system. Incidentally, he proposes to relate this latter prospect to the duration of the War and the continuance of their support of Nazism—a weapon of political warfare the effectiveness of which should not be missed.

There can be no question as to the complexity of the issues involved, but while on many matters of detail, particularly in regard to the re-education of Germany, further inquiry is still necessary, decision and action rather than inquiry are the primary need. Both must, it is true, follow on a careful weighing of the whole situation, but the consequences which may follow from a mistake in policy and in action must be no excuse for indecision. We must make up our minds as to the possibility and desirability of attempting the re-education of Germany and the practicability of holding down a disarmed and resentful Germany over a period of decades. Having made that decision, we must formulate the policy which will secure the conditions giving it the best prospects of success.

DYNAMICS IN PSYCHOLOGY

Dynamics in Psychology
By Wolfgang Koehler. Pp. 120. (London: Faber and Faber, Ltd., 1942.) 8*s*. 6*d*. net.

IT is good to meet a book of this quality in days when the non-academic world is measuring the value of science too exclusively by its immediate practical applications. If this attitude were to prevail indefinitely the future of science would be dark, and the prospects of the applied sciences themselves clouded. Psychology to-day is enjoying an unexpected and dangerous popularity because it has been found useful in application. Mental testing, industrial psychology, psychotherapy, these are the fields in which psychologists are considered to justify themselves. We are entitled to feel satisfaction that we have made some contribution to current problems; but it is necessary to insist that their scientific interest is soon exhausted, and that further developments in the sphere of practice are dependent upon the construction of a coherent body of theory. Prof. Koehler's book is very remote from a warring world, but because it deals with fundamental issues it may be regarded as ultimately of greater importance than the technical successes by which psychology is now at length securing a place in the sun.

This book contains no revolutionary addition to *Gestalt* theory, but it is of great value by reason of the new assembly of perceptual data adduced, and the hard and honest thinking which the writer brings to bear upon them. It may be commended as an introduction to *Gestalt* psychology, since the limitation of the problems dealt with brings out the more clearly the fundamental issues involved. Speaking very broadly, the author, who believes that scientific explanation means more than the colligation of facts, holds that psychological structures are causally dependent upon physiological processes, and that the latter are essentially electrodynamic in character. Thus it seems psychology is reduced to physiology, and that in turn to physics. If the facts are so we must accept them, but a reduction of this kind has some awkward situations to face. Do I know this book ? If so, that psychological experience is dependent upon electric fields in my cortex, and my knowledge of that explanation upon others, and so on in bewildering succession. We suggest that much more detailed knowledge of facts is required before resolute theorizing along this line is justified, and that we must exercise caution lest we mistake formal analogies for actual identity. Though they may be causally related, there remains a fundamental qualitative difference between the phenomenon called 'knowing' and its physiological correlate; and any form of epiphenomenalism has to meet the question of the origin of such an irrelevance as consciousness.

Having entered this *caveat*, we can pay tribute to the author's positive contributions. It is, we believe, inevitable that there should be an integration of the different sciences (though its achievement lies far ahead) and the methods and concepts of one science should be made to enrich others. Koehler is undoubtedly right in his insistence that psychologists should accept this principle and face the heavy task of acquainting themselves with other sciences, and his development of this theme in detailed examples is excellent. He takes obscure facts of visual perception, argues from their properties to the existence of electro-dynamic fields in the cortex (so indicating possible lines of research to the physiologist), then from the nature of the fields deduces the existence of other unsuspected visual phenomena, and empirically confirms his hypothesis by showing their existence. Incidentally, he gives a brilliant exposition of scientific method as a combination of hypothesis and factual observation. He claims with justice that his school has made the field-concept central in psychology. But field-concepts are unhappily difficult to handle. Probably we should do better to work with it for the present in the traditional spheres of psychology, avoiding attempts to construct theoretical relationships to other fields until field theories have become a real part of our intellectual furniture. We must note, too, the observations of Head and Lashley on the effects of ablation of cortical areas. These indicate that the organism must be regarded, not as a neutral region in which fields develop, but as a nodal and formative factor in its relations to the world. Gestalt psychology is still weakest on the functional side.

The latter part of the book takes up problems of memory, and is admittedly more tentative than the earlier. Koehler again applies the hypothesis of electro-dynamic fields, coupled with that of 'traces'. Here the physiology is thoroughly speculative, and the attempt is, in the reviewer's opinion, premature. The physiology necessary to explain remembering has still to be commenced, and so far as explanatory theory is concerned psychology is in little better case. But since the author makes no claim to deal comprehensively with memory it would be unjust to criticize the book for incompleteness. The chapters on perception offer sufficient material to the reader. The exposition is fully up to Koehler's high standards of lucidity, conciseness and firm thinking. He sets a model of careful yet bold argument, which those who challenge his conclusions would do well to imitate.

A. W. WOLTERS.

PRACTICAL AIR NAVIGATION

Astronomical Air Navigation

A Comprehensive Handbook embodying the Latest Principles for Practical Navigators, Instructors and Students. By Squadron-Leader Ronald Hadingham. Pp. xi+132. (Kingston Hill: The Technical Press, Ltd., 1943.) 10s. 6d. net.

MANY books on air navigation have been published since the beginning of the War. The essential feature of this volume is that it has been written for practical navigators by a practical navigator of great experience. It contains no mathematics, and the theoretical aspects of the subject are reduced to a minimum, though the fundamental basic principles are simply and clearly explained. Methods of working and reducing sights are fully described and special attention is given to practical work in the air.

The author's own experience has made him familiar not only with the difficulties that the beginner encounters but also with the precautions that must be taken by the practised navigator to obtain an accurate determination of his position. The arrangement and use of the Air Almanac and the Air Navigation Tables are fully dealt with, and fourteen specimen pages from the two publications are reproduced. A number of practical examples illustrate the methods and principles, and a description is given of the standard sextant used in the Royal Air Force and of the use of star curves. The volume can be strongly commended to the air navigator as being clear, concise, helpful and essentially practical.

It is unfortunate, however, that the chapter on astronomy—included to give the navigator a brief summary of facts about the sun, moon, planets and stars—was not revised by an expert. The author is here on less familiar ground, and many of the statements are inaccurate and misleading. After referring, for example, to the great distances of the stars, the comment is made: "Little wonder that distant starlight 'twinkles' unsteadily, while the closer planets shine boldly in contrast". The rings of Saturn are described as rings of vapour. Referring to the magnetic fields of sunspots, it is stated that "Sometimes the polarities are not balanced, however, as often occurs in the large very active groups, and it is under these conditions that we feel a magnetic influence on the Earth". It is also said that when the spot group crosses the central meridian of the sun, its lines of magnetic force fall on the earth.

It is to be hoped that these and some other errors will be corrected in a future edition, as also some eccentricities of English, such as the repeated use of *data* as a singular noun and the use of *focii* as the plural of focus.

H. SPENCER JONES.

INDUSTRIAL MYCOLOGY

An Introduction to Industrial Mycology

By George Smith. Second edition. Pp. xii+260. (London: Edward Arnold and Co., 1942.) 20s. net.

THIS is one of those useful books about one branch of science written for those who have specialized in another sphere of knowledge. Modern industrial chemistry accords an increasing allegiance to the natural laboratory facilities provided by several species of fungi. Citric acid now owes little but its name to citrus fruits, and is produced from sugar by a mould fungus, usually a species of Aspergillus. Gluconic acid, glycerol, fats, proteins, vitamins and antibacterial substances such as the newly discovered penicillin can now be added to the time-honoured production of alcohol as examples of mycological chemistry. Fungi can also interfere in a negative way with stored organic products.

Mr. Smith's book describes the principal fungi the activities of which are harnessed by chemists at the present time. Zygomycetes, Ascomycetes including the yeasts and related fungi, and Fungi Imperfecti are the main groups concerned, while separate chapters are devoted to Aspergillus, to Penicillium and its related genera, and to the Hyphomycetales. The classification is chiefly that of Saccardo, though several useful practical keys have been adapted from other authors. Descriptions of the species are quite adequate, and the use of fermentation tests or special methods to induce spore formation is frequently discussed. The illustrations, 136 in number, are a very attractive feature of the book. There are excellent half-tone blocks of photomicrographs taken at certain precise and selected magnifications, and are readily comparable one with another. The student is thus shown what he should actually see under the microscope provided his technique is adequate for this type of detailed study.

General mycologists will find considerable taxonomic interest, for many of the species considered in the book are little known outside the urge of necessity provided by industrial application, or the rare experience of a lexicophilic student of Saccardo or Rabenhorst. The teacher will also find it rich in material which can be used to provide that thrill in secondary education which is, alas, so often lacking. Mycology could surely be taught more interestingly through its human implications, and there must be few students too blasé to take delight in the mycological production of a soft lemon centre fit for the most expensive chocolate, or the quick production of a vitamin, or the mycelial short-circuiting of a synthesis laborious by all other methods.

The chapters on technique are detailed only in the methods which the mycologist superposes upon those of the bacteriologist. Preparation of slide cultures, for example, receives more minute treatment than routine sterilization. Physiology of the mould fungi is also dealt with in similar fashion, and an interesting short account of the mutual interaction of two species of fungi raises some potent questions in fungal ecology. The maintenance of culture collections and the control of mould growth are two further important industrial features dealt with in the volume. Perhaps the least satisfactory section is that on the industrial uses of fungi, but this is in no way the fault of the author. It is probable that few branches of knowledge are more concealed from the scientific world by the vested interests of patents than this small section of mould mycology.

Industrial mycology is an expanding science, and this volume will doubtless expand *pari passu*, for it provides an excellent basis. For a work of reference it is easy to read, and the reader is led beyond the immediate horizon by good lists of references, and a section upon mycological literature. This includes descriptions of general works, monographs, books on systematic mycology and on applied mycology, journals and periodicals. The volume is a very welcome and pleasing exposition of a little-known subject. J. GRAINGER.

EARLY BRITAIN

Britain B.C.

By S. E. Winbolt. (Pelican Books, A.106.) Pp. 160. (Harmondsworth and New York: Penguin Books, Ltd., 1943.) 9*d.* net.

THE writing of a really satisfactory elementary and popular book on the prehistory of Britain in some 150 pages is not an easy task. The author must have read everything himself and yet must not put in too much. The temptation to include details which are out of place in a small work is almost irresistible. Again, he must make up his mind whether or not to assume any previous knowledge of general prehistory on the part of the reader. If he does not, much of the small space at his disposal will have to be occupied with matter not exactly relevant to the immediate subject in hand. On the other hand, if he assumes a knowledge of prehistory and then merely details the more important discoveries made in Great Britain, he lays himself open to the criticism that he has merely produced a dull catalogue; yet such method of approach *can* produce a volume very useful both to the student and the holiday maker.

In the present book, little or no such general knowledge is assumed, and as a result there is rather a lack of balance. The stresses, too, do not perhaps always leave the right impression on the uninitiated reader; special finds such as those of decapitated skeletons are worthy of notice, but their occurrence does not necessarily mean that there was an epoch when mankind universally practised this custom (p. 97). The short book-list, too, presents anomalies. Parkyn's book is long out of print, but Baldwin Brown's work is not mentioned. Neither Childe nor Wheeler, who have both written volumes on parts of Britain, are mentioned. There are plenty of elementary first-rate English text-books on prehistory generally, so why cite Peyrony's "Éléments de Préhistoire". Finally, when describing a site or a find, surely it would be well to quote the opinion of the author who has made the matter his chief study, rather than the casual opinions of other writers.

But in spite of these criticisms, Mr. Winbolt has made a great effort to include a lot of facts in the compass of a small volume, and there will be many people who will find his little work an introduction to a fascinating hobby-subject which can well be studied in Britain. M. C. BURKITT.

ADVANCED ORGANIC CHEMISTRY

A Text-Book of Organic Chemistry

By the late Dr. Julius Schmidt. English edition by Dr. H. Gordon Rule. Fourth edition, revised and extended. Pp. xxvii+923. (London and Edinburgh: Gurney and Jackson, 1943.) 28*s.* net.

THE late Dr. Julius Schmidt's "Kurzes Lehrbuch der organischen Chemie" had established a considerable reputation as a text-book for students of advanced organic chemistry before Dr. H. Gordon Rule translated it into English in 1926. In this edition Dr. Rule acted as editor as well as translator, and in the later English editions of 1932 and 1936 his editorial role became more and more pronounced. He spared no pains to keep the work up to date, to preserve a proper balance between various sections of the subject, and to do justice to the work of British and American organic chemists.

In the fourth English edition these fundamental aims are worthily maintained. There will be widespread regret among organic chemists that Dr. Rule did not live to see the printed version of this last evidence of his sound judgment, progressive outlook, and keen enthusiasm in the cause of organic chemistry. The production of the book was supervised by his colleague, Dr. Neil Campbell, from Dr. Rule's complete revised manuscript; another colleague, Dr. E. G. V. Percival, revised the section dealing with carbohydrates.

The general character of the book remains unaltered. It is planned methodically upon a structural basis, leading to a systematic survey of the manifold organic types. There is an adequate, but not obtrusive, treatment of the physical background, and the stereochemical and biochemical aspects of the subject are well developed. Among themes of current interest which come under discussion in the new edition we may mention resonance, the electronic theory of benzene substitution, deuterium compounds, chromatography, synthetic plastics, chemotherapy, vitamins, hormones, and steroids.

The book is well printed, well documented, and well indexed. It is one of the most useful text-books of advanced organic chemistry available at the present time. This opportune edition will come as a boon to hard-worked honours students as a standard and up-to-date treatment of a vast and rapidly expanding branch of science; others will welcome it as a valuable book of reference. JOHN READ.

Frequency Modulation

By K. R. Sturley. Pp. 58. (London : The Hulton Press, Ltd., 1942.) 2*s*. 6*d*. net.

THE communication of intelligence by means of radio frequency electric waves is effected either by interrupting the waves into groups of long and short duration, or by varying the amplitude, frequency or phase of the waves in some controllable manner. Radio telephony as used for broadcasting and other purposes all over the world has hitherto been based very largely upon the varying amplitude type of modulation. The principles of frequency modulation, in which the frequency of the carrier waves is varied about its mean value at a rate depending upon the modulation requirements, have been known for many years and have been applied to such purposes as the determination of the height of the ionosphere or the altitude of aircraft. During the past decade, however, work conducted notably n the United States has demonstrated the merits of frequency modulation for broadcasting, particularly n the improvement of the signal-to-noise ratio obtained at the receiver. A number of broadcasting stations using frequency modulation on the ultra-short wave-length band below 10 metres have been in operation for some years.

With this growth of radio technique, it is natural hat there should be a demand for literature in various forms. It is therefore of interest to direct attention to a very useful monograph recently pubished by Dr. K. R. Sturley. This booklet, of a very handy size, is based upon a series of articles published in *Electronic Engineering*, and completely evised for publication in its present form. It deals in the first place with the general principles and the advantages and disadvantages of frequency- and phase-modulated transmissions, and with methods of producing the required modulation. The remainder of the monograph then discusses the frequency modulation receiver, including a full analysis of the circuit requirements, and typical calculations which should prove of great value to the designer of such a receiver. While no frequency-modulated broadcast transmissions have yet been authorized in Great Britain, many students and workers in the subject will be indebted to the author of this booklet for having collected together and summarized in such a clear manner the state of our present knowledge.

The editor of *Electronic Engineering* states that his is intended to be the first of a series of technical monographs on specially interesting radio and electronic subjects, to be issued in a uniform style. Additions to the series will be awaited with interest.

The Journal of the Institute of Metals

Vol. 68, 1942. Edited by N. B. Vaughan. Pp. xxxii+430+37 plates. (London : Institute of Metals, 1942.)

IT is, of course, impossible to give an adequate account of the papers comprising this volume without occupying considerable space. The practical importance of the information given, however, may be indicated by brief references to some of the conclusions reached, and invidious distinction may be avoided.

In a series of papers on bearing metals, a laboratory test is described for measuring the adhesion of bearing metal to backing material on laboratory specimens, and another for examining the strength of the bond at different locations in manufactured bearings. The first is used to examine the effects of time and temperature of pre-tinning and composition and thickness of coating on the bond obtained with different bearing metals. One investigator shows how poor adhesion of tin-base bearing metals may frequently be caused by the presence of shrinkage cavities at the inter-face between white metal and shell, resulting from unsatisfactory casting conditions. Railway practice in the use of white metal bearing materials is described with admirable frankness, and details are given of two methods now in production for the separation of white metal and bronze bearings.

Investigations on the factors influencing the cold pressing properties of duralumin sheet have led to improvements, resulting from a modified rolling technique, to the development of a more favourable microstructure, in which the inter-metallic compounds are distributed with greater uniformity. The mechanical properties of metal foils have also received detailed attention, as a result of which tests have been devised, throwing light on the fundamentals involved and enabling a quantitative determination to be made of the factors governing service behaviour in such applications as bottle-caps.

Although our knowledge of the effects of impurities on the properties of copper is already very extensive, it has not been necessary until recently to pay much attention to selenium and tellurium, which have now become important, being present in certain coppers from Empire sources. Two papers in the present volume go a long way towards supplying the remaining information needed before best use can be made of these important raw materials.

Among other interesting and valuable contributions, there must be mentioned the fascinating story of a thirty-year investigation into the factors which affect the grain size of rolled aluminium. H. W. G. H.

Radio Goes to War

By Charles J. Rolo. Pp. 245. (London : Faber and Faber, Ltd., 1943.) 8*s*. 6*d*. net.

IT is proper that inventors be informed of the uses and abuses of their inventions. The last ten years has seen a change in the function of the verbal material of broadcasting. While this aspect in many countries remained somewhat pedestrian, the new Continental ideologies found in it a weapon of propaganda and confusion, sufficiently novel and devastating to sabotage whole nations. All present belligerents now use this bloodless weapon on a scale and with policies comparable in magnitude to those controlling the active forces on land and sea and in the air. Monitoring posts eagerly analyse up to a million words a day emanating from the enemy, inserting replies in a hundred daily news bulletins in perhaps forty different languages, all subtly urging some section of a community to do something of which it can have no independent judgment.

The author has great experience in this field and shows how the technique has developed during the present hostilities, where it wins and where it fails. He gives detailed factual histories of "Lords Haw-Haw" and "Hee-Haw", the V-campaign, the rallying of the Free French, the subversive secret stations, the hit and parry between Berlin and the Kremlin; and the feeble imitations by the Japanese, all conducted through the submissive ether. The only sign of civilization is the mutual reluctance to jam. Few can appreciate the intensity of this radio war. For the future, everyone should know that the radio is a trigger to be pulled at any moment to stir up the latent forces on the Continent of Europe on behalf of those oppressed. L. E. C. HUGHES.

FLUORESCENCE OF ORGANIC MOLECULES*

By DR. JOSEPH WEISS
University of Durham

FLUORESCENCE is the emission of light of a colour generally different from that of the incident radiation. The question arises: which organic substances might be expected to exhibit fluorescence, or perhaps, under what conditions do certain organic substances show fluorescence.

Although this problem has not yet been solved, our increasing knowledge of the mechanism of light absorption in molecular systems makes it possible to outline a few general ideas regarding the fluorescent properties of organic molecules.

Theoretically, fluorescence represents a simple quantum process where an absorbed light quantum is again emitted as light, generally of a somewhat different frequency. In fact, however, this represents the exception rather than the rule, as a large number of organic molecules which absorb in the visible region of the spectrum or in the near ultra-violet do not show fluorescence. In these cases one may say that the fluorescence is 'quenched' and the absorbed light energy appears in other forms of energy, usually as heat.

There are obviously two ways in which the optical (electronic) excitation energy can be converted into heat:

(*a*) Internal quenching, within the molecule itself.

(*b*) External quenching, which occurs in those cases where the molecule shows fluorescence under certain conditions but this fluorescence disappears in the presence of other (interacting) substances.

In the latter case one is in a position to study the conditions under which quenching occurs, and the study of external quenching has proved very useful in the elucidation of these problems, particularly in solutions. A good example of this is provided in the quenching of fluorescence of various dyes, methylene blue, thionine, etc., by simple ions such as I^-, Fe^{2+}.

A closer study of these reactions has shown[1] that the mechanism of light absorption and quenching can be represented by the following simple elementary processes (where D represents dye molecule):

(1) light absorption : $D + h\nu \rightarrow D^*$ (excited dye) ;
(2) fluorescence emission : $D^* \rightarrow D + h\nu_1$;
(3) quenching : $D^* + Fe^{2+} \rightarrow D^- + Fe^{3+}$.

This is followed by the formation of the colourless leucobase of the dye:

$$D^- + H^+ \rightleftarrows DH\,; \quad 2DH \rightarrow D + DH_2 \text{ (leucobase).}$$

The nature of the quenching process (3) was first revealed by the use of a very strong light source which showed a (reversible) bleaching of the solution, whereas in the following dark period the leucobase is re-oxidized to the dye by the Fe^{3+} formed, thus completely restoring the initial state.

Another important type of quenching occurs, for example, in the case of the polycyclic carcinogenic hydrocarbons or chlorophyll, which are of some biological interest. The fluorescence of these substances is quenched by molecular oxygen[2,3], and as we have found recently also by nitric oxide, whereas carbon monoxide and nitrous oxide are without effect[3].

The elementary process of quenching can be represented by the following sequence of reactions (HC stands for the organic molecule) :

(4) light absorption $(HC) + h\nu \rightarrow (HC)^*$;
(5) fluorescence $(HC)^* \rightarrow (HC) + h\nu_1$;
(6) quenching
  (*a*) by oxygen $(HC)^* + O_2 \rightarrow (HC)^+ + O_2^-$;
  (*b*) by nitric oxide $(HC)^* + NO \rightarrow (HC)^+ + O_2^-$.

In general, reactions (6*a*) and (6*b*) are completely reversible in the dark, that is, if oxygen or nitric oxide is replaced by an atmosphere of nitrogen, or is pumped off, the original fluorescence is completely and instantaneously restored. Under certain conditions (with prolonged irradiation) the primarily formed peroxides or nitroxides can be stabilized to some extent and have in some cases been isolated in pure form, thus also supporting the quenching processes proposed above.

Many substances which fluoresce in solution lose this power to some extent with increase in concentration. This phenomenon of 'self-quenching' has been known for some time, but was not well understood Pringsheim[4] has pointed out recently that it cannot be due to the simple formation of associated molecules as there is a shortening of the actual life-time of the excited state which runs parallel to the quenching He suggested that 'self-quenching' in the case o anthracene in solution is connected with the photochemical formation of dianthracene.

A detailed study of the self-quenching of a number of carcinogenic hydrocarbons and of chlorophyll in solution has led us to the conclusion that this apparently represents quite a general phenomenon The elementary process of 'self-quenching' is represented by:

$$\text{(7) self-quenching: } (HC)^* + (HC) \rightarrow (HC)^+(HC)^- \qquad (HC)_2 \rightarrow 2(HC),$$

resulting in the primary formation of a photo dimer In general, this reaction is reversible in the dark although in certain cases (for example, anthracene) a partial stabilization of the dimer may occur.

The 'self-quenching' process often depends on the medium (solvent). Stabilization of all these photochemical association products also depends greatly on the partner in the three-body collision. Ou experiments indicate that there are only certain molecules (probably mainly another (HC) molecule which are appreciably efficient as third bodies.

Another consequence of 'self-quenching' is seen in the fact that some substances which do not show fluorescence in the solid state often exhibit fluorescence in mono-molecular (adsorbed) layers. Some dyes (for example, crystal violet) which do not fluoresce in solution often show fluorescence when embedded in a solid substance (for example, boric acid, sugar, gelatine). It can be shown that when there is no free diffusion, as in these solid phosphors the relationship between fluorescence yield (γ) in the stationary state and the concentration of the dye (c is given by

$$\gamma = \frac{k_1}{1 + k_2 c\,(1 - e^{-\omega c N})}, \qquad (8)$$

where N is Loschmidt's number. This differs by th term within the bracket from the ordinary (hyperbolic) quenching equation. This term takes into account the fact that self-quenching in the rigid medium occurs only when there is at least one dy molecule within the sphere of action (ω) of the fluorescent molecule. For small concentrations of the dye, the fluorescent yield is therefore increased as compared with liquid solutions.

---

* Substance of a lecture delivered to the Chemical Society of the University of Manchester, on February 17

The foregoing discussion leads to the conclusion that absorption of light results either in (*a*) fluorescence, or (*b*) photochemical interaction. This fact has often not been recognized in the past mainly for the following reasons: (i) Sometimes (usually) the intensity of the light source is too weak, so that permanent changes do not manifest themselves. (ii) The photochemical primary processes are often completely and rapidly reversible in the following dark periods.

There is one characteristic feature common to all organic molecules which show appreciable fluorescence in the visible or near ultra-violet, namely, all these molecules (dyes, aromatic hydrocarbons, etc.), without exception, are composed of systems of conjugated double bonds.

It is well known that the non-localized π-electrons present in these systems behave in many respects like electrons in a metal. The electron levels in these molecules correspond to the Brillouin zones in a metal[5], and the mechanism of fluorescence and quenching outlined above can also be interpreted from this point of view.

When a light quantum is absorbed in such a molecule, the electron will make a transition from a state in the filled band to a corresponding state in the unfilled upper band. If the electron recombines again with the hole left in the lower band, this will result in fluorescence emission (Fig. 1*a*).

On the other hand, quenching occurs if the excited molecule comes in contact with another molecule (or ion), which provides another localized electronic level (normally vacant) between the allowed bands into which the excited electron from the upper band can be trapped (Fig. 1*b*), corresponding to reactions of the type (6*a*), (6*b*); or there is the other possibility that an electron of the quenching substance (in collision with the excited dye) neutralizes the hole left in the lower band (Fig. 1*c*, corresponding to the reactions of type 3).

In both cases, either the excited electron or the hole created by the absorption of light is removed and fluorescence is prevented.

Similar considerations can be applied to the question of 'internal quenching' in molecules, and this leads directly to the problem of fluorescence and chemical structure (in the absence of external quenching).

As pointed out above, the presence of loosely bound electrons is apparently a necessary condition for fluorescence. If the electrons were actually 'free', then primarily absorbed light would *always* have to appear as 'fluorescence' because 'free electrons' cannot absorb radiation (on account of the conservation of energy and momentum). Light energy can only be absorbed by the electrons if there is some coupling between electronic motion and molecular vibrations.

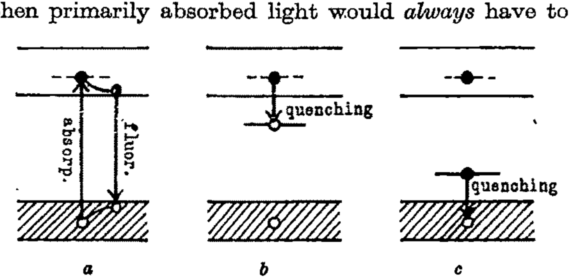

Fig. 1. SCHEMATIC REPRESENTATION OF THE ABSORPTION OF LIGHT, EMISSION OF FLUORESCENCE AND QUENCHING IN MOLECULES WITH SYSTEMS OF CONJUGATED DOUBLE BONDS.

(*a*) emission of fluorescence (in the absence of quenching); (*b*) quenching by a substance with an empty electronic level into which the electron can fall; (*c*) quenching by a substance which has a level with loosely bound electron.

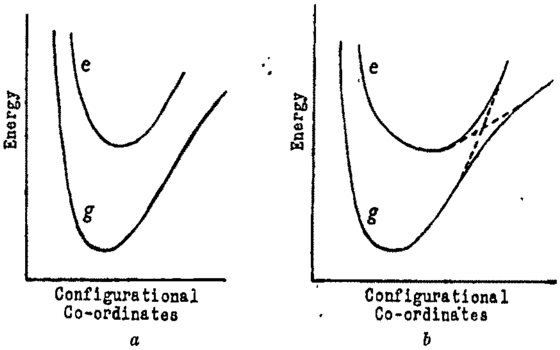

Fig. 2. SCHEMATIC REPRESENTATION OF THE POTENTIAL CURVES OF THE GROUND STATE (*g*) AND THE EXCITED STATE (*e*): (*a*) for small interaction; (*b*) for strong interaction (crossing).

So long as there is complete resonance within the molecule, there is no appreciable coupling with the molecular vibrations, and the optical excitation of a loosely bound electron will not result in any appreciable change of the nuclear configuration. Consequently, the potential curve of the excited state will not differ appreciably in shape from that of the ground-state (Fig. 2*a*).

The situation is different when one introduces an atom or group into the molecule (for example, a halogen, nitro group, etc.) which has a certain 'electron affinity' or which in some other way exerts strong forces towards the excited electron, thereby providing localized levels where the electron can be 'trapped' (similar to the case of Fig. 1*b*). In this case these strong forces will tend towards a distortion of the nuclear configuration, and this will in general result in a 'crossing' (near approach) of the two potential curves which will now be very different in shape (Fig. 2*b*). This 'crossing' of potential curves is an essential condition for the (non-adiabatic) transformation of electronic excitation energy into vibrational energy or chemical energy, which then appears as heat[6]. This is shown, for example, in the case of fluoresceine sodium, which has a high fluorescence yield in solution, whereas this yield is strongly decreased in its halogen derivatives (eosin, erythrosin). It is clear also that self-quenching effects are enhanced in molecules with 'trapping centres'.

There is also an important difference in the behaviour of the π-electrons in cyclic structures as compared with conjugated chains. In cyclic structures the electrons are circulating uniformly around the rings, as is also shown by the large diamagnetic anisotropy of these molecules[7]. This is different in the chains because there the phase of the electron waves at the ends of the chain, and the electron density, are determined by the boundary conditions, that is, the electrons are only 'free' towards the centre of the chain, but more or less localized at the ends. For localized electrons the probability of a radiationless transfer is considerably greater and this is presumably the reason why fluorescence is more often found in cyclic structures than in chains (for example, polycyclic aromatic hydrocarbons compared with polyenes, fluorescein compared with phenolphthalein).

Molecules which are capable of fluorescence can often act as photosensitizers in photosensitized oxidations or in photographic emulsions, and they are sometimes also of some biological interest (for example, chlorophyll, carcinogenic hydrocarbons). As illustrated above, the striking feature of all these fluorescent molecules is that they are capable of reversible oxidation-reduction processes involving only simple electron transfer reactions.

It has been shown that these reactions are also responsible for their photosensitizing action[1], and their biological significance is presumably also a result of this 'electronic reactivity'.

THOMAS JEFFERSON AS NATURAL PHILOSOPHER

By Dr. HARLOW SHAPLEY

Harvard College Observatory

PREVIOUS speakers [in the symposium arranged by the American Philosophical Society during April 22–24 to commemorate the two hundredth anniversary of the birth on April 13, 1743 of Thomas Jefferson] have easily encroached upon my subject, doubtless finding it difficult to consider the versatile Jefferson as a lawyer, a farmer, a diplomat, a traveller, without discussing also his thoughts and acts in the broad field of natural philosophy. Thus the famous contribution on the mould-board of the plough has been discussed, as well as the observations and speculations on climate, ethnology, and palæontology. My remarks can therefore be in the nature of miscellaneous supplementary notes.

Jefferson had a telescope. He was keenly and practically interested in surveying and navigating, and in the astronomical measurements required by such work, but he was in no sense an astronomer. His curiosity about the non-terrestrial was, however, healthy; and his admiration for the famous self-taught David Rittenhouse of Philadelphia brought him into frequent contact with practical and speculative astronomical questions. He used his telescope during the annular eclipse of the sun of September 17, 1811, and reported his observations both carefully and modestly. Towards the end of his life he used the telescope to watch, from his mountain home, the workmen building the University of Virginia.

Like all daring thinkers and workers in the pioneer days of so many of the sciences, Jefferson sometimes went to extremes. These misadventures were so few, compared with his successes, that one should not mention them at all except to prevent the impression that he was actually omniscient and infallible. Naturally he became cautious. When, for example, spectacular reports were made about shooting stars, he was sceptical. According to the Honourable S. A. Mitchill's account, Jefferson declined to accept the story of the meteoric fall in Connecticut in December, 1807. He did not like this Connecticut story; and he did not like the way the Connecticut Yankees pronounced their Latin, either. There was, indeed, no love lost, for it is notorious how vigorously much of Connecticut disliked this Virginia advocate of religious tolerance. They reported showers of stones from the Connecticut clouds—he discounted the claims at once and said, according to Mitchill, that five words would be sufficient for a response. They were short words—"It is all a lie!"

But later, when the evidence concerning the meteoric fall became clearer, Jefferson reconsidered the matter and recommended that competent authorities of the American Philosophical Society might look into it. He first pointed out, however, that the sending of the Connecticut stones to Congressmen was not necessarily the most profitable procedure, in view of the limitations of those particular gentlemen. The letter on the meteoric stones to Mr. Daniel Salmon is dated February 15, 1808, and is worth quoting as an illustration of Jefferson's scientific attitude.

"Sir, I have duly received your letter of the 8th instant, on the subject of the stone in your possession, supposed meteoric. Its descent from the atmosphere presents so much difficulty as to require careful examination. But I do not know that the most effectual examination could be made by the members of the National Legislature, to whom you have thought of exhibiting it. Some fragments of these stones have been already handed about among them. But those most highly qualified for acting in their stations are not necessarily supposed most familiar with subjects of natural history; and such of them as have that familiarity, are not in situations here to make the investigation. I should think that an inquiry by some one of our scientific societies, as the Philosophical Society of Philadelphia for example, would be most likely to be directed with such caution and knowledge of the subject, as would inspire a general confidence. We certainly are not to deny whatever we cannot account for. A thousand phenomena present themselves daily which we cannot explain, but where facts are suggested, bearing no analogy with the laws of nature as yet known to us, their verity needs proofs proportioned to their difficulty. A cautious mind will weigh well the opposition of the phenomenon to everything hitherto observed, the strength of the testimony by which it is supported, and the errors and misconceptions to which even our senses are liable. It may be very difficult to explain how the stone you possess came into the position in which it was found. But is it easier to explain how it got into the clouds from whence it is supposed to have fallen? The actual fact however is the thing to be established, and this I hope will be done by those whose situations and qualifications enable them to do it."

Much earlier than the epoch of the meteor shower and the annular eclipse, Jefferson had developed a considerable interest in certain problems of cosmogony. During his long stay in France he had become acquainted with many of the leading men of science. Among them was the famous Buffon, the great naturalist and the encyclopædic writer on scientific subjects. Buffon got some of his biological specimens from Jefferson, and was generous enough to write, "I should have counseled you, sir, before publishing my Natural History, and then I should have been sure of the facts." It was a fine compliment, in the Parisian style. It is scarcely imaginable now that a man of science would seek the advice of a leading national politician in order to get his facts straight.

The "Epoques de la Nature", written by Buffon about 1780, received excited attention throughout Europe. It was but one part of the "Histoire Naturel" with which he was long associated and which appeared during forty years in almost numberless volumes. One particular theory in "Epoques de la Nature" disturbed Jefferson. He wrote about it, in 1784, to the Rev. James Madison:

"It has occurred to me to reflect a little more on Buffon's central heat than I did at the moment of our conversation and to form an opinion different from what I then expressed. The term 'central heat' does not of itself give us a false idea of Buffon's hypothesis. If it means a heat lodged in the center of the Earth and diffusing its warmth from thence to the extremeties, then certainly it would be less in proportion to the distance to that center, and so forth. Of course less under the equator than the Poles, on high mountains than in deep valleys. But Buffon's theory is that this Earth was once in a state of hot fusion, and that it has been, and still continues to be cooling. What is the course of this process? A heated body being surrounded by a colder one, whether solid or fluid, the heat, which is itself a fluid, flows from the colder body equally from every point of the hotter. . . ."

Jefferson, of course, subscribed to the current fluid theory of heat, universal at that time; but it is noteworthy that he also states one of the basic laws of thermodynamics. He goes on in the letter to Madison to reason that on the Buffon hypothesis the earth should be hotter at the poles than at the equator, contrary to observation, and contrary to the conclusion derived by Buffon, who says that the earth, being thinnest at the poles, will cool sooner there than under the equator where it is thicker. Jefferson concludes, "If my idea of the process of cooling be right, his is wrong and his whole theory in the Epochs of Nature is overset."

In general, the natural philosophy of Jefferson was of the practical sort. Apparently he was somewhat soured by the speculators on the origin and age of the earth. But he rather skilfully avoided the controversy of his time as to the origin of fossil shells on the mountain tops. He would not commit himself that they were remnants of the sea-line of the time of Noah's Flood; or evidence of the rising ocean waters having covered the peaks; or one of those strange manifestations of the All-wise which permits shell-like formations to grow through the ages in the same way that queer rock formations and crystals are formed without associated organisms.

His interest in geology was chiefly confined to a practical interest in mining and in the related field of palæontology. His enthusiasm for fossil bones led him to the inquiries and writings and collecting that have given him right to the title of founder of American palæontology. As has been told fully elsewhere, and many times, he brought along to the scientific men and museums of Philadelphia a collection of remarkable bones when he journeyed to that city to become the Vice-President of the United States. Those fossils, one hundred and fifty years later, are on proud display. Later he built up at Monticello a much greater palæontological collection. It dominated the famous residence.

The steam engine was one of the practical scientific developments of his time that had a peculiar appeal to Jefferson. It inspired him to seek the possibility not so much of transportation nor of man's manufacturing, but rather the emancipation of the individual citizen from the drudgery of chores. He viewed the advances of science in terms of the practical problems of his plantation. If the tea kettle could only be developed into a practical steam boiler, the water could be pumped to the tops of the houses; the household machinery could be operated by water power, and hands released for the fields. Jefferson went from France to England especially to see Watt and his famous engine; but the canny inventor, or his advisers, saw to it that this shrewd and inventive Virginian did not get a close look at the details.

Thomas Jefferson was interested in the precious metals from two points of view—the coinage of the United States, and the mining industry. While Vice-President of the United States he was attracted by the problems of the copper mines at Newark, New Jersey. Miss Adams has just recently published from the Boston Public Library a letter, heretofore unpublished, touching on this subject. Jefferson wrote to Elisha Boudinot in Newark concerning the resources of the Schuyler copper mines, which operated some three miles north of the town from 1719 until 1775, and later. There is one sentence in that newly published letter which indicates an early contact of the Roosevelt family with the White House. Was it prophetic? The sentence is, "As soon as you receive Mr. Roosevelt's answer I shall be further thankful for the communication of it." A matter of incorporation was involved, and one may assume that the awaited answer came in good time from Nicholas Roosevelt, who was the great-great-grand-uncle of some later tenants of the White House.

In 1790, when George Washington was President of the United States and Thomas Jefferson the Secretary of State, the latter was asked to make a report on weights and measures suitable for the new federation of States. The subject naturally interested one with such wide scientific and social interests as Jefferson, and one who had had close contacts with the reforms and innovations in France. He made recommendations that in a way resulted in the founding of the Bureau of Standards. More than twenty years later, Jefferson was writing to Dr. Robert Patterson concerning the project that the American Philosophical Society should look into the subject of fixing standards of measures, weights, and coins. He was a member of a committee charged with examining the problem. With a fine sense of the disadvantage of working with a committee from a distance, Jefferson modestly remarked, in the introduction to a long letter on the subject: "Isolated as is my position, I am sure I can offer nothing but what occurred to the committee engaged on it, with the advantage on their part of correction by an interchange of sentiments and observations among themselves. I will, however, hazard some general ideas, because you desire it, and if a single one be useful, the labor will not be lost."

It is of interest that a major part of this letter is devoted to the question of the appropriate diplomatic techniques necessary to get co-operation in Europe with an American innovation. All must be handled delicately, with full consideration of the prides and prejudices and sensitive vanities of the Governments of the foreign nations. He writes:

"With England, our explanations will be much more delicate;"—he is writing about the possibility of international agreement on a decimal system for weights and measures—"they are the older country, the mother country, more advanced in the arts and sciences, possessing more wealth and leisure for their improvement, and animated by a pride more than laudable . . . The subject should therefore be opened to them with infinite tenderness and respect, and in some way which might give them due place . . . ." His approach reminds one of the techniques and tendernesses necessary at the present time in advocating international fellowship.

Jefferson makes an interesting commentary ("Writings", **13**, 105) on the English gentleman as an amateur man of science. "We (in Virginia) are all occupied in industrious pursuits. They abound with persons living on the industry of their fathers, on the earnings of their fellow-citizens, given away by their rulers as pensions. Some of these, desirous of laudable distinction, devote their time and means to the pursuits of science, and become profitable members of society by industry of a higher order."

Returning to his consideration of units of weights and measures, Jefferson proposed, in one crystal clear sentence, unmatched in my experience for simplicity and completeness, the following:

"That our unit of measure then be a pendulum of such length as in the latitude of 45°, in the level of the ocean, and in a given temperature, shall perform its vibrations, in small and equal arcs, in one second of time."

His uncommon gift for clear writing could not be better illustrated. But his proposal was not accepted. His arguments against the unit of the one ten-millionth part of the distance from the pole to the equator were to the point. But it takes more than clarity and logic to simplify the deeply rooted system of weights and measures.

Jefferson's "Notes on Virginia" were among his most noteworthy writings. To me they demonstrate more clearly than anything else that if he had been free from his national political life he could have readily developed into one of the leading men of science of his time and country. His "Notes" touched all phases of the natural history of the region, and dealt with its people and its government. There were many editions, many translations. But he viewed his accomplishments with modesty. On September 25, 1785, he wrote to Francis Hopkinson: "I have sometimes thought of sending a copy of my Notes to the Philosophical Society as a tribute to them, but this would seem as if I considered them as worth something, which I'm conscious they are not. I will not ask you for your advice on this occasion, because it is one of those on which no man is authorized to ask a sincere opinion. I shall therefore refer it to further thought."

How many an editor has wished that his scientific contributors would refer their compositions to further thought!

The "Notes" were written in the war years, 1781 and 1782, and therefore we should make some allowance for Jefferson's rather stinging comparison of *little* America with Great Britain and great France, so far as the production of genius is concerned. His war-time comments on Britain: "The present war so long having cut off communication with Great Britain, we are not able to make a fair estimate of the state of science in that country. The spirit with which she wages war, is the only sample before our eyes, and that does not seem the legitimate offspring either of science or of civilization. The sun of her glory is fast descending to the horizon. Her philosophy has crossed the Channel, her freedom the Atlantic, and herself seems passing to that awful dissolution whose issue is not given human foresight to scan." For four hundred years worried men have predicted the impending dissolution of Britain. She has always been in a state of rapid decline!

One could continue at length with quotations that show the sensitiveness, the vast learning, the curiosity, and the originality of this astonishing Virginia farmer. He had, as they say, pretty nearly everything. In the field of natural philosophy he had caution and daringness, inquisitiveness and a willingness to change his mind in the light of new facts or as a result of further thought. What we would now call proper scientific methods and attitudes appeared to be instinctive with him.

His scientific creed is illustrated in his response to the Abbé Raynal's taunt, that America had produced no poet, no mathematician, or man of genius in any art or any science. In his "Notes on Virginia", Jefferson asked for time with regard to the poet; but pointed to Washington and Franklin (as well he might) as leaders in the soldier's craft, and the craft of physics; and concerning the Philadelphia astronomer he wrote, "We had supposed Mr. Rittenhouse second to no astronomer living; but in genius he must be the first, because he is self-taught. As an artist he has exhibited as great a proof of mechanical genius as the world has ever produced. [A famous orrery is referred to.] He has not indeed made a world; but he has by imitation approached nearer its Maker than any man who has lived from the Creation to this day." In a footnote he points out that the European nations traverse the globe with the aid of Hadley's quadrant, which was actually invented by the American Godfrey.

But to return to the scientific creed. The Abbé Raynal later withdrew his taunt with regard to the North Americans; but still disparaged the South Americans. In a footnote Jefferson questions the sufficiency of the Frenchman's knowledge, and the depth of his research on the subject concerning which he was writing. He indicated how the nationality and conditions of the interpreter might well affect the interpretation, and concluded with the unforgettable statement:

"A patient pursuit of facts, and a cautious combination and comparison of them, is a drudgery to which man is subjected by his Maker if he wishes to obtain sure knowledge."

THE WAY AND SPIRIT OF SCIENCE*

By Generalissimo CHIANG KAI-SHEK

Chairman of the Military Affairs Commission of the Republic of China and Supreme Commander of the Chinese Armies

The Scientific Approach

PROCEED from the immediate to the distant, from the low to the high; attain the great through the small, the difficult through the simple. To accomplish great and important things, it is necessary to start from the nearest, simplest, and most minute matters, enlarging and expanding gradually in systematic order.

---

* Abridgment of an address by Generalissimo Chiang Kai-shek, given in 1942; translated by Huang Hsing-Tsung and Dr. Joseph Needham, F.R.S. Note that the word "Way" has a special significance in Chinese philosophy. The address is posted in all Chinese Government laboratories and workshops.

Competence in small things precedes competence for big affairs; first know how to do commonplace things well; afterwards talk of doing work of special importance. Know how to solve small and easy problems; afterwards you may be successful in rare accomplishments. Never run after speculations and far-reaching conclusions, missing out immediate stages and hoping for lucky shots. Your work will only be superficial; short cuts will not lead to the desired aim, and nothing solid will be accomplished.

The Scientific Spirit

In order to investigate thoroughly all the phenomena of man and Nature, our attitude towards anything should be, not only to attempt understanding of what is not understood, and to make experiments where the previous experiments have not been satisfactory; but also to understand further what is commonly supposed to be already understood, and to improve further those experiments which have already been commonly considered satisfactory. The more knowledge grows, the more the lack of it is felt. The greater one's accomplishment, the more intensely the smallness of one's ability is realized. But it is through this very feeling of inadequacy and insignificance that knowledge and achievements can continually progress.

Never be satisfied with obtaining one result or even a small success. Whatever be the department of knowledge one is investigating or whatever kind of work one is to do, it is necessary before starting to consider properly the facts of the case, avoid all vagueness in defining the aim and be sure about the method to be employed. Once started, be determined to carry the project through, working unceasingly and meeting every obstacle with undaunted resource.

Many young men of to-day have no understanding of this principle. They will start to study a subject or work on a project, but when they meet the slightest obstacle or disappointment, instead of holding on doggedly and industriously, they will merely skip the difficulty and turn over to some other easier problem. This mental unsteadiness, chopping and changing time after time, will never bring any result.

There are also many who have as their main object in life the attainment of wealth or high official position, and if they find themselves engaged in work where these aims seem to have little or no hope of realization, they will discard it without any consideration, however important it may be, and creep into some new path. Such opportunists, consulting only their own selfish interests, have no responsibility to the country and the people.

The Scientific System

Limitations. In doing anything we must first know the limitations of the question; in other words, one must be quite clear about one's object and aim. This is of prime necessity, for one can then concentrate time and energy upon possibilities within the frame of reference. Thus one can avoid all distractions from other sources; and one will not try to do several things at once. If we think of attacking one problem to-day, another to-morrow, and still another the day after to-morrow, finally nothing will be accomplished. In investigations and affairs it is essential to define the central idea. Only if this is done can we distinguish between the roots and branches of things, avoiding confusion between the first and the last. A clear idea of the order of things, which stands the test of practice, is required for the success of any research.

Management. All reasonable scientific organization must satisfy the following requirements: (*a*) a vertical definite dendritic order; (*b*) a horizontal intimate co-ordination. The vertical order embodies the relation between the upper and the lower, the deriving to the derived, levels of organization. Such relation must be well understood before the organization can be effectively controlled and steered with ease. The horizontal co-ordination embodies the relation between each small part of the organization to every other part, so as to give harmony in operation. Such relations must be intimate before the different portions can achieve complete co-ordination, and the organization run with maximum efficiency.

Recording and Preparation. Before beginning work on any subject, collect every type of material available, examine it carefully, and presuppose all possible situations which may be encountered at different later stages, using all possible intelligence and resourcefulness. Consider the preparation of different types of formulæ to meet different situations so that at any stage of the work the most satisfactory formula can be produced. Only those who are thoroughly industrious and persevering in thought, only those who have different solutions and formulæ prepared beforehand, can meet every situation with calmness and ease. However difficult the matter in hand may be, in the end they find the solution which carries them through.

Division of Labour and Co-operation. The advance of human civilization has been entirely due to division of labour and co-operation. Whether it be knowledge or practical affairs, division of labour is necessary for specialization, and co-operation is necessary for success. For the intelligence and ability of one single man are limited; hence each man has to select a particular branch of knowledge for investigation or a special type of practical work to do; only then is the highest efficiency attained. Then the results of different investigations have to be unified and co-ordinated, and the entire whole of knowledge and achievements makes real progress. We Chinese suffer from a great lack of co-operation in knowledge and affairs. In our scholarly researches there is not enough discussion and mutual understanding; and in our affairs there is little sympathetic and helpful co-ordination; thus the research spirit is low and few things are done well and effectively.

Research. The progress of science and the improvement of the lot of man have been due to the efforts of research. These were not accomplished by people who are content to work to strict office hours. In the West, work is carried on not only in the normal working hours, but even free time is not wasted. For example, Sundays have been found just the right time for intellectual investigations. If we are to save our country, we must break through the present lethargic and pessimistic psychology, and cultivate an industrious and persevering spirit, dedicating oneself to research with all one's heart and mind.

Experimentation. Many of the results of investigation and observation are only theories which have to stand the test of experiment before it can be shown whether they are correct and suitable for practical purposes. If experimentation shows flaws in the theory, then it is necessary (according to the facts of the case) to study more carefully, trying various improvements until as satisfactory a hypothesis is obtained as possible. If one still fails, the reasons for failure must be further inquired into, and corrections made accordingly. The ideal type of research worker is one who stands firmly by the scientific attitude (the objective outlook), observes facts and circumstances objectively and with humility, and draws his conclusions therefrom. Then only will there be any hope of knowing the truth.

Analysis and Statistics. When any plan or project of work shows development at the experimental stage, whether good or bad, one must collect and analyse the mass of material on hand, find out where the defects or good points are, decide whether the plan is workable and how far progress has been made, and in which direction and along what lines future developments are to take place. This statistical and analytical ability and the power for precise decision are fundamental in the success or failure of our research or practical work. Without the analytical and decisive mind it will not be possible to see clearly and objectively the relevant facts, and one falls into a mental state of chaos and disorder, failing to discover any likely approach to a successful conclusion.

Improvements and Inventions. To be conscious of mistakes is the most important factor in making progress. So in all our analytical examinations it is imperative to find the causes of these mistakes; only in this way shall we be able to find the required improvements. We must also persevere to discover those new principles, new methods, and new factors which are essential for general progress.

Conclusions. We live in an era of difficulty, suffering and danger. To be able to shoulder the heavy responsibility of reviving our nation and completing our revolution, we must have at all costs a clear idea of the content and meaning of science; we must propagate the spirit of science; and we must utilize the methods of science; so that one man will be as efficient as ten, and in one day ten days work will be done. While we are fighting intensely at the front for the mode of life we want, we cannot remain stationary at home; if we do not progress we shall degenerate; if we cannot achieve success we shall be ruined; if we do not prosper we shall be crushed; if we still refuse to gather our full strength our very existence will become impossible. From this day onwards, whatever it is we have to do, and whoever is doing it, there should be no more inefficient half-heartedness and no more spirit of fatalistic resignation.

OBITUARIES

Prof. David Hilbert, For.Mem.R.S.

News has reached Great Britain that Prof. David Hilbert, of Göttingen, died recently. He was born on January 23, 1862, and was a mathematician of tremendous power who ranged over a wide field and had an unusual influence on present-day mathematics. An indication of the breadth of Hilbert's influence is the number of mathematical topics which are associated with his name. For example, we have Hilbert space, Hilbert inequality, Hilbert transform, Hilbert invariant integral, Hilbert irreducibility theorem, Hilbert base theorem, Hilbert axiom, Hilbert sub-groups, Hilbert class field. Again we recall his contributions to the "Yellow-Backs": "Methoden der Mathematischen Physik" (with Courant), "Grundlagen der Mathematik" (with Bernays), "Anschauliche Geometrie" (with Cohn-Vossen), "Theoretische Logik" (with Ackermann).

The fact that Hilbert was able to produce outstanding original results in a large number of different branches of mathematics and mathematical physics is most remarkable in our times. It was made possible by his ability to concentrate completely on one subject for a time; when he had finished, he rarely returned to it or even cared to hear about it, not even recognizing his own results. However, when Hilbert did become interested in a subject, he was able to indicate so many possible lines of development that mathematicians were kept busy for decades afterwards on new problems.

There can be few mathematicians nowadays whose work does not in some way derive from Hilbert. His personality and naïve enthusiasm attracted to Göttingen many pupils and followers who will always delight in recalling their experiences there and in passing on some of the Hilbert anecdotes. Hilbert's devotion to mathematics was complete: he allowed no prejudices, racial or otherwise, to interfere. For example, despite violent opposition from his colleagues, during the War of 1914–18 he insisted on delivering a eulogy on Darboux and on Emmy Noether receiving the *venia legendi* at Göttingen.

While it is not possible to give here an account of Hilbert's work, it is worth while recording some of the main topics on which he concentrated at various periods: invariant theory, algebraic number theory, diophantine equations, integral equations, foundations of geometry, mathematical physics, calculus of variations, foundations of mathematics. A detailed study of his papers reveals the continuous development of his thought from "theology" back to "theology". In honour of his seventieth birthday a three-volume edition of his papers was published. Reviews of the volumes by Prof. L. J. Mordell, to which those who wish for a more detailed account of his work should refer, appeared in the *Mathematical Gazette* in 1932, 1934 and 1936. I had the privilege of being closely associated with Hilbert in the preparation of this edition. In conversation, Hilbert often affirmed that, much as he admired every branch of mathematics, number theory was for him the most attractive. By number theory he meant algebraic number theory rather than the number theory typified by Waring's theorem, for which he nevertheless found the first proof and by which he is perhaps best known in Great Britain to-day. His work on Waring's problem was totally unconnected in content and time from his main work on number theory. It is interesting to recall that, in connexion with a lecture by Prof. R. Fueter at the 1932 Zurich Congress, Hilbert asserted that the theory of complex multiplication (of elliptic modular functions) which forms a powerful link between number theory and analysis, is not only the most beautiful part of mathematics but also of all science.

Among Hilbert's papers, I will mention only a lecture in Paris in 1900, in which he stated his famous series of twenty-three problems. These were the problems which he considered most significant in mathematics at that time; not isolated questions but problems of such a general character that their solution was bound to have an enormous influence on the shape of future mathematics. The present time seems an opportune one, since so many mathematicians have given up their usual sort of mathematics, for another Hilbert to state the present position of the original problems, and to present a new series and thereby to orient the activities of mathematicians of the future.

OLGA TAUSSKY.

Dr. T. T. Groom

THOMAS THEODORE GROOM was born at Wellington, Shropshire, on May 16, 1863, and died in Oxford on March 26, 1943. After studying at the University of Heidelberg and University College, London, he entered St. John's College, Cambridge, in 1885 with an exhibition, and was afterwards awarded a foundation scholarship. He obtained a first class in the Natural Sciences Tripos Part 1 in 1887 and in Part 2 (Geology) in 1889, and gained the Harkness scholarship for geology and palæontology. In the same year he took first-class honours in the examination for the London B.Sc.

Groom's first post was as demonstrator in zoology at Leeds under Prof. L. C. Miall. He next became professor of natural history at the Royal Agricultural College, Cirencester. In 1899 he left Cirencester for University College, Reading, where he was lecturer in geology and zoology. In 1906, at the invitation of Prof. Lapworth, he went to Birmingham as lecturer in geology, and remained there until Lapworth's retirement in 1914, when he moved to Oxford, where he spent the rest of his life.

At first Groom's interests seem to have been equally divided between geology and zoology, but eventually the attractions of geology prevailed. Although his qualifications in both geology and zoology seemed to fit him especially for research in palæontology, his principal work was in field geology.

While still an undergraduate, Groom wrote a paper on the corallian echinoid Pelanechinus, of which he discovered one of the only three specimens known. By a detailed study of its structure he brought forward new evidence to show that this genus belongs to the Echinothuridæ, of which it is the earliest representative, living forms being found in the deep sea. In Pelanechinus he proved, for the first time, the existence of pedicellariæ in fossil echinoids.

After taking his degree at Cambridge, Groom spent a year at the Naples Zoological Station and investigated the early stages in the development of Cirripeds. The results of this work, for which he was awarded the D.Sc. of London, were published in the *Philosophical Transactions of the Royal Society*, **185** (1895), and *Quarterly Journal of Microscopical Science*, **37** (1895). Of Groom's work in geology his unravelling of the complex tectonics and geological history of the Malvern and Abberley Hills is of outstanding merit. The results of this investigation were published in a series of papers during the years 1899 to 1902 (*Quart. J. Geol. Soc.*, **55**, **56**, **57**, **58**) and a general summary of the work, including the Ledbury district, was given in "Geology in the Field" (1910), p. 698. In collaboration with his friend, Philip Lake, Groom wrote on the geology of the Silurian districts of Corwen and Glyn Ceiriog in North Wales (*Quart. J. Geol. Soc.*, 49, 64).

Groom's interests were wide. In palæontology, in addition to the early paper on Pelanechinus, he described new Cambrian hyolithids, trilobites and ostracods (1902), while in petrology he wrote on the igneous rocks associated with the Cambrian of the Malvern Hills (1901) and on a tachylite from Carrock Fell (1889). In geomorphology he gave an account of the effects of faults on the character of the seashore (1895). From 1907 until 1917 Groom spent much time in investigating the beds forming the boundary of the Silurian and Old Red Sandstone in the Llandeilo and other districts of South Wales. It is greatly to be regretted that this work was left unfinished and no account of it published. After 1910 his only publication was a short paper, in conjunction with W. K. Spencer, on Ordovician starfishes which he had discovered in Shropshire (*Geol. Mag.*, 1934). Groom was a stamp collector and made some contributions to the literature of philately. His notebooks, zoological preparations and a few rock-slices were bequeathed to the Sedgwick Museum, Cambridge. The main part of his geological collection was left to the University Museum, Oxford. Owing to his long retirement from active work, Groom was personally but little known to the younger geologists of to-day. Those of his contemporaries who survive cherish the remembrance of a good friend and a genial companion.

H. WOODS.

Dr. E. C. V. Mattick

DR. ELFREIDA C. V. MATTICK (*née* Cornish) died in Reading on July 19, 1943. She was educated at Colston's School, Bristol, and took her qualifying degrees at the University of Bristol, working with Prof. J. W. McBain on a thesis dealing with the colloidal properties of soap solutions. She later took her doctorate at the same University. But she will best be remembered for her very long association with the National Institute for Research in Dairying at Shinfield, where she took up work on a Ministry of Agriculture Scholarship in 1913. For thirty years, but for a few months, she worked at Shinfield; in earlier years with Dr. Stenhouse Williams and Mr. J. Golding on the effects of heat treatment on the nutritive value of milk and later on the chemical changes taking place in the ripening of cheese, on the fat-splitting enzymes present in milk and milk products, on vegetable sources of rennet and on many other chemical and biochemical problems of practical importance in dairying.

Her first husband, Mr. Lionel Venn, was killed very shortly after her marriage during the War of 1914–18. Later, she married Dr. A. T. R. Mattick, now head of the Bacteriology Department at Shinfield.

During the last years of her life Dr. Mattick suffered from very bad health, but her enthusiasm for research and unfailing courage gave her the strength to continue her investigations in the laboratory until only a short time before her death. This triumph of a resolute mind over a failing physique was noted and admired by her colleagues, and her own slowly progressing illness never disturbed that kindliness and consideration for others for which she will long be remembered by all who knew her.

G. W. SCOTT BLAIR.

WE regret to announce the following deaths:

Sir Stopford Brunton, Bt., the well-known Canadian mining geologist, on July 25, aged fifty-eight.

Prof. J. Gibson, emeritus professor of logic and philosophy in the University College of North Wales, Bangor, on August 1, aged seventy-eight.

NEWS AND VIEWS

Substitute Materials

THE unfounded belief that a substitute is necessarily inferior to the material it displaces takes an unconscionable time to die. It is not long since a well-known member of Parliament objected to the incorporation of synthetic aneurin (vitamin B_1) into our bread, to replace that taken out with the germ, on the ground of adulteration. Replacement of a natural constituent by an identical artificial one cannot now reasonably be considered fraudulent; in fact, it is often economically advisable, and some of the substitutes that are in use as a consequence of war-time scarcity promise to outlive the lean years through which we are now passing. A good account of the more important of these is given by Dr. C. H. Desch in a brochure entitled "Substitute Materials in War and Peace", which he has written for the Royal Institute of International Affairs (Oxford University Press. 9*d*. net). Owing to war-time restrictions, very few details are given, but the bird's-eye view presented of substitutes for natural petrol, rubber, fibres, metals, and of the entirely new materials termed, somewhat erroneously, 'plastics', will convey to the layman all he needs to know for the appreciation of the present position in this very active field of inquiry.

Among the less well-known facts mentioned by Dr. Desch, the following may be cited: In the autumn of 1941, Germany was using producer-gas for running 150,000 lorries; many more were on order and also 20,000 new agricultural tractors with the same means of propulsion. In the United States, synthetic resins have become even scarcer than the aluminium they were designed to replace. An artificial fibre, made entirely from coal, limestone and chlorine, has been made in Germany since 1939; it is used for protective clothing, fishing nets and chemical filters. Some 10,000 tons of 'fodder yeast', first made on a large scale in Germany during 1914–18, was being produced at Regensburg in 1939. Nickel in the Axis countries has been largely replaced by chromium and molybdenum, obtained within occupied regions. There is no evidence that the quality of German aircraft is suffering in any way from lack of suitable alloy steels, but for steel-making there is probably a shortage of manganese, for which no satisfactory substitute is known.

In Great Britain much economy has been effected by reducing the number of steel specifications from 2,000–3,000 to 85, and further reduction is possible. Copper and 'stainless' steel for making resistant chemical plant have been economized by using mild steel with a surface-layer of the more valuable metal, rolled on to it during the manufacture of the plates. Difficulties have been encountered in finding a satisfactory substitute for tin in making tin-plate and for bearings. In the United States, plants are being constructed to produce annually 800,000 tons of synthetic rubber from petrol and 200,000 tons from alcohol, prepared from grain. Japan is said to be using her superabundance of rubber by distilling it to produce petrol. Of all substitutes now in use, synthetic resins are considered to have the greatest probability of survival, and as mineral resources gradually decline, as they inevitably must, greater use will be made of substitutes, and particularly of those which can be produced from the renewable raw materials provided by Nature.

Britain Needs a National Policy of Technical Education

THIS is the title of a pamphlet (price 6*d*.) published by Messrs. Pitman's and Son. It is a noteworthy addition to the many documents which have been issued to show the needs and possibilities of a reconstructed educational scheme, since it outlines strong arguments for the need for giving very special attention to the development of technical education. It reminds us that "Our education policy is being shaped now. Technical education is an integral and essential part of it, the importance of which must in no circumstances be overlooked or underestimated". No one will deny that, especially if it be realized that "There is no future of any consequence for Britain save as a highly industrialized nation". The pamphlet shows how technical education has been neglected in the past and underlines the disastrous policy which followed the Education Act of 1902 and separated secondary from technical education. Despite that neglect the magnificent work of the technical institutions since 1939 is made clear, and emphasis is laid on the fact that "the needs of peace will be as urgent and all embracing as those of war". Recommendations which will lead to the desired end are set out in detail. Many of them have already appeared in other documents dealing with educational reconstruction, but they cannot be too often repeated. Rather mysteriously the title page tells us only that the author is "A Student of the Future", but the pamphlet appears to be an expression of the views of the Association of Technical Institutions and the Association of Principals of Technical Institutions.

American Education and the War

IT is significant that the American magazine *School Life* has, for the duration of the War, been replaced by *Education for Victory*, "the official biweekly of the United States Office of Education Federal Security Agency". The aim of this interesting periodical is to spread information throughout the forty-eight States about war effort in the schools and colleges of each State. Prominence is given to a declaration of the National Education Association as to the spirit of school teaching in war-time. However it may be for the fighting forces, the emotions of hatred and revenge have no place in the schools, especially among the younger children. "The spiritual casualties of war will be great enough and lasting enough without any help from the teaching profession." Rather let the young people be taught a strong and positive love of freedom and fair play, and the strength of their opposition to slavery and injustice is assured. So *Education for Victory* tells of all that American schools and colleges are doing to help the war effort. Such activities as school gardening, and the securing of food for school lunches, appear to be carried out on an immense scale. The ever-pressing necessities of the war situation have directed closer attention than ever before to the problem of adequate nutrition. In still more direct ways than these, the schools are doing their share of effort. High-school students may now take the ground-school test of the Civil Aeronautics Administration. A few months ago, we are told, high-school students could only dream about aviation. Now tens of thousands of boys are studying pre-flight aeronautics, and 200 boys are actually learning to fly. *Wings for Victory* publishes also detailed information about what the higher educational institutions are doing for the War. Nearly five hundred of them have been approved tentatively, and subject to inspection will take allotted parts in war-training programmes. Obviously the normal course of scientific and technical education is being suspended, but on the other hand an immense stimulus is being given to forms of training that are destined to remain after hostilities have ceased.

Russian Interest in Mathematical Statistics

A CABLE from Prof. Alexander Schneiderman informs us that the centenary of Rothamsted Experimental Station was celebrated on July 21 at a meeting held in the Moscow Scientists' Club. Prof. Dmitri Prianishnikov, the 'father of Russian agricultural chemistry' and one of Timiriazev's closest collaborators, presented a historical review in which he indicated the part Rothamsted had performed in laying the foundations of chemistry applied to agriculture. Experimental fields in emulation of the classical trials of Lawes and Gilbert had been laid out in several countries; the Russian Institute for Research in Fertilizers has its own experimental field and conducts experiments at three hundred places in various soil zones of the Union.

Particular attention was given to Rothamsted's development of statistical methods, including the analysis of variance, in the design and interpretation of field experiments—a subject which hitherto has been noticed (by Russians) only by V. Romanovsky. Prof. Vassily Nemchinov read a paper on the significance of the work of the Rothamsted Statistical Department, founded in 1919 at the instigation of Sir John Russell. Prof. Nemchinov said that the idea of organizing a statistical department was characteristic of Rothamsted, as it involved collaboration between field workers, mathematicians, and pure biologists. A new branch of statistical theory had been developed, and had been very fruitful in estimating the reliability of results of both field and laboratory work.

Beit Memorial Fellowships for Medical Research

IN their annual report the trustees of the Beit Memorial Fellowships for Medical Research note the election this year again, as in 1942, of three past fellows to the fellowship of the Royal Society, namely, I. de Burgh Daly (fellow 1920–23); W. G. Penfield (1921); and S. Zuckerman (1934–37). Out of the twenty-five present fellows there are now sixteen seconded for whole-time war work. The following elections were made, with permission for each fellow to be seconded at any time for war duties: *4th Year Fellowships* (£500 a year): Dr. J. J. D. King, to continue his studies of dental caries and parodontal disease, at the Nutritional Laboratory of the Medical Research Council; P. C. Williams, to continue his studies of natural and synthetic œstrogens, at the Courtauld Institute of Biochemistry, Middlesex Hospital; *Junior Fellowships* (£400 a year): Margery E. M. Cutting, to study the physiological metabolism of organs in infancy, at the Department of Medicine, University of Cambridge; Dr. A. Kleczkowski, to study serological reactions in reference to size and shape of antigen and antibody particles, at Rothamsted Experimental Station, Hertfordshire; Dr. G. J. Popjak, for an experimental study of fatty and degenerative changes in the kidney, at St. Thomas's Hospital Medical School; Dr. Ethel G. Teece, to study the chemical structure of Gram-positive and negative micro-organisms and to develop antibacterial agents, at the Department of Chemistry, University of Birmingham.

Future of Analytical Chemistry

THE Council of the Society of Public Analysts and Other Analytical Chemists has had under consideration the desirability of the formation, within the Society, of groups or sections dealing with special subjects or branches of analytical chemistry. Many members of the Society have been concerned with the implications arising from the recent rapid development of analytical chemistry and the probable continuation of such development in the post-war period, and the need of some measure of federation and co-ordination of specialized branches of analytical chemistry was apparent. Since one of the objects for which the Society was established, as set forth in its memorandum of association, is "to encourage, assist and extend the knowledge and study of analytical chemistry", the Council believes that this purpose can be best achieved by the institution of groups within the framework of the constitution of the Society. Negotiations are already in progress with the Microchemical Club with a view to that body becoming a Microchemical Group of the Society, but the formation of other Groups also, as may be deemed desirable, within the Society will be encouraged, and proposals to this end will be submitted to a special meeting of the Society in the autumn.

National Institute of Social and Economic Research

THE annual report for 1942 of the National Institute of Social and Economic Research refers to the removal of the Institute to 2 Dean Trench Street, Westminster, where the new premises have permitted a thorough re-organization of the library. This has been re-classified and re-catalogued, and an accessions programme worked out to fill up the more serious gaps in books, periodicals and official publications. The Institute is prepared to make it available for reference to research workers in Government service who may wish to supplement the resources of their departmental libraries. Research work during the year was almost entirely a continuation or extension of programmes either under way or planned, but the first issue of the Register of Research in the Social Sciences, the new version of the summary of research in progress and in plan, was completed in December and has been circulated confidentially. The Saving and Spending Survey begun in 1940 was concluded in October, and the inquiry into National Health Insurance undertaken by Prof. H. Levy was sent to the press early this year. Dr. Baykov's study on the development of the Soviet economic system, which has taken the form of a thoroughly documented essay on the experience of planning in the U.S.S.R., was concluded by the end of the year. Dr. Singer completed in November a short descriptive study of standardized accountancy in Germany and Prof. Findlay Shirras brought to a close in the autumn the "Federal Finance Enquiry". Mr. A. Shenfield completed a report on "The Impact of War on Coventry: a Study in Industrial Dislocation", covering the war period up to the end of 1941.

Three inquiries, on national expenditure, output, and income, 1920–38, on the measurement of national income of selected Colonial territories, and on the burden of local taxation, which had already begun, were continued throughout the year and are being carried on in 1943. The second of these was originally concerned with Northern Rhodesia and Jamaica, but has now been extended to Nyasaland in view of the valuable data on that Colony which became available during the year. With regard to the third, a paper on the expenditure of county boroughs in England is now in the press and the full inquiry will be published under the title "Wealth and Poverty in Local Government", as there are insufficient data to permit a calculation of the local tax burden comparable with that made for the national tax survey in "The Burden of British Taxation". Of the inquiries upon which work only started in 1942, that into profit margins is the most significant. Other plans which came into operation during the year were Dr. R. R. Kuczynski's study of post-war population problems, and studies in aspects of commercial policy, directed by Dr. P. Barrett Whale. Two continuous projects were initiated in 1942: the observational study of the effects of the War on the credit policy and credit mechanisms of the City of London and the "Weekly Diary: Summary of Economic and Social Changes". It is intended to continue the former for the duration of the War, and a full-length descriptive and analytical summary is expected to result.

Vital Statistics of Canada

According to the twentieth annual report on vital statistics for 1940 and the preliminary annual report for 1941, both recently issued by the Canadian Bureau of Statistics, the population of the Dominion has increased in the last twenty years from 8,776,000 in 1921 to 11,443,000 in 1941. The largest populations were found in Quebec (3,329,000) and Ontario (3,765,000). Although the birth-rate for 1941 (22·3 per 1,000 population) showed a slight increase, the rate has fallen from an average of 24·1 in the quinquennium 1926–30 to 21·5 in 1940. The rate was highest in New Brunswick (25·9) and lowest in British Columbia (17·4). The stillbirth-rate in 1941 was 2·6 per cent of all births. As regards infant mortality the provisional figure for 1941 was 60 per 1,000 live births and the rate of 56 for 1940 was the lowest recorded. The maternal mortality-rate for 1940 was 4·0 per 1,000 births and that for 1941 was 3·5. The marriage-rate showed a progressive increase from 7·3 per 1,000 population in the period 1926–30 to 10·8 in 1940 and 10·7 in 1941. The general death-rate was 9·6 per 1,000, the lowest rate being found in Saskatchewan and in Alberta.

Sources of Engineering Information

The fifth number of the ASLIB War-time Guides to British Sources of Specialised Information (March 1943) deals with engineering other than electrical. These are listed under Government departments; professional, research and trade organizations; and educational organizations and technical educational organizations. The list of Government departments is not comprehensive, but is confined to sources of information still usually accessible. All references to industrial firms have been omitted. Electrical engineering and telecommunications are covered by Guide No. 3. An additional section lists a number of organizations dealing with fuel, raw materials, transport, etc., which while not directly related to engineering are concerned with materials and aspects of work of immediate interest to engineers. The section devoted to periodicals lists separately those printing abstracts or lists of references; periodicals issued by professional and industrial organizations; other trade and technical periodicals; selected periodicals relating to auxiliary interests; engineering annuals; and annuals dealing with auxiliary interests.

Recent Earthquakes

The U.S. Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the epicentres of two recent earthquakes. The first of these was on June 8 at about 20h. 42·2m. U.T. and occurred near latitude 19° N., longitude 116° E. This is in the South China Sea, west of Luzon in the Philippine Islands. The second was on June 9 at about 3h. 6·7m. U.T. and had its epicentre near latitude 9° N., longitude 120° E., which is in the Sulu Sea north-east of Borneo. On the morning of Friday, July 16, a strong earthquake was felt throughout the Island of Jamaica. The epicentre was some ninety miles from Kingston in the Balaclava district, where some damage was done to property though there are no reports of any loss of life.

Announcements

The Association of Scientific Workers (West Midland Area) has arranged an open conference on "Science under Fascism and Democracy", to be held at the Town Hall, Birmingham, on August 22 at 3 p.m. The Lord Mayor of Birmingham (Councillor W. S. Lewis) will open the conference, and the chair will be taken by Prof. M. L. E. Oliphant. Among the speakers who will deal with the sharp contrast in the approach to science and its applications, and also the treatment of scientific workers, in Democratic and Fascist countries, are Prof. J. B. S. Haldane (Great Britain), Dr. J. H. Hildebrand (United States), P. H. Yap (China), M. Fournier (France), Dr. A. van Anrooy (Holland), Dr. B. Schober (Czechoslovakia), Dr. A. Fischer (Austria), and Dr. J. G. Siebert (Germany). In the evening following the conference, films will be shown depicting scientific activities in many countries.

The fifth supplement to the "British Pharmaceutical Codex" contains new monographs describing the insecticides derris and lonchocarpus, and new regulations which are introduced because of the shortage of rubber and quinine. Where the "Codex" insists on rubber, the supplement allows other materials to be used, and where the "Codex" includes quinine the supplement omits it except in the cases where it is considered essential. This supplement also includes a cumulative index to all the five supplements which have been issued.

The New York Academy of Medicine, in co-operation with the State Department of Health, the City Department of Health and six of the leading voluntary organizations of maternal welfare and child health, recently celebrated the hundredth anniversary of the publication by Oliver Wendell Holmes of the paper entitled "The Contagiousness of Puerperal Fever".

Erratum. In the letter entitled "Production of Ion Clusters by X-Rays" (Nature, June 19), sixth line from bottom of first column, p. 698, for "$B_Z = 11{\cdot}2$ ev." read "$B_Z = 11{\cdot}2\ Z$ ev.".

War-time Growth of Schoolboys

THE rationing and restriction of many of our common foodstuffs has prevented the free choice of food to which we were all of us accustomed before the War, but it has handicapped some of the community much more than others. The public schools have had a difficult time because boys of 14–18 require more total food than the average holder of a ration book, yet the schools have no means of obtaining meals for their boys outside the ordinary rations. The question therefore has arisen as to whether this has made any difference to the boys' rate of growth. Are public school boys now as tall and heavy as they were before the War? The pre-war and war-time weight and height records of boys at two public schools have been submitted to statistical analysis. Both schools take a serious interest in the way their boys are fed.

GROUP *A* (BOYS AGED 14–15 YEARS).

Year	Average weight in January of each year. (lb.)	Average increment during the year. (lb.)	Average height in January of each year. (in.)	Average increment during the year. (in.)
1939	115·5	12·9	64·9	2·4
1940	113·9	12·0	64·4	2·5
1941	116·9	12·8	65·2	2·4
1942	116·4	12·8	65·3	2·1
1943	113·8		64·0	

GROUP *B* (BOYS AGED 15–16 YEARS).

Year	Average weight in January of each year. (lb.)	Average increment during the year. (lb.)	Average height in January of each year. (in.)	Average increment during the year. (in.)
1939	123·8	11·6	66·8	2·0
1940	125·6	10·3	67·1	1·7
1941	126·5	10·3	67·1	1·9
1942	128·0	10·0	67·5	1·7
1943	129·2		67·4	

The rate of growth during the year January 1939–40 has been compared with the rates of growth during the three following years. The boys were divided into two age-groups, *A* and *B*. Group *A* comprised all boys who became fifteen during the course of each year of investigation, and group *B* all boys who became sixteen during each year.

Very similar results were obtained at both schools and average results for one school are shown in the accompanying tables. At this school there were about a hundred boys in each age-group in each of the years 1939–43. There has been no significant decrease in the height and weight of these boys during the past three years; the 15–16 year-old boys are in fact taller and heavier now than were boys of a corresponding age before any food restrictions were imposed. Hence we may conclude that, given reasonably good catering and management, the rationing system should not have interfered with schoolboys' growth. This speaks well for the system of rationing, or the brains behind it; but it may be pointed out that if no outside sources of food are available, the catering must be good to make the present rations the basis of an adequate diet for a group of healthy young men or boys.

Radioactivity and the Completion of the Periodic System

IN connexion with the article by Prof. F. A. Paneth[1] in NATURE of May 23, 1942, I would like to direct attention to the fact that the systematics of isotopes acquires a more simple and logical form if, besides the usual formation of nuclei by addition of a neutron (${}_0^1n$) and a proton (${}_1^1p$), we assume the possibility of the formation of new nuclei by addition of a hypothetical particle (${}_{-1}^{1}a$) of unit mass and charge equal to $-e$, which may be called the aproton-type formation of nuclei.

In a recent paper[2] I have shown that, if all isotopes are plotted on the graph (Z, A), some regularities in the position of stable nuclei may be noticed. These regularities may be considered as a consequence of the existence of the following scheme in the sequence of addition of elementary particles in the process of formation of new nuclei:

$$\left.\begin{array}{l}\text{(1) From hydrogen to oxygen } n\rightarrow p\rightarrow n\rightarrow p\rightarrow\ldots\\ \text{(2) From oxygen to titanium } 2n\rightarrow 2p\rightarrow 2n\rightarrow\ldots\\ \text{(3) From titanium to uranium } (2n \text{ or } 4n)\rightarrow\\ \qquad\qquad\rightarrow(2p(a) \text{ or } 4p(a))\ldots\end{array}\right\}\quad(1)$$

where n, $2n$, $4n$ . . . denote the addition of one, two, four . . . neutrons one after another without interruption; p denotes the addition of a proton; $2p(a)$, $4p(a)$ the addition of two or four protons one after another, the last of which may or may not be replaced by an aproton.

Fig. 1 shows a part of the graph (Z, A), namely, from $Z = 78$ to $Z = 94$. Stable isotopes are denoted by crosses, β-active isotopes by circles, and stable isotopes not yet found, but expected according to the above scheme (1), by dots. As this graph shows, all known stable isotopes in this range, without exception, agree with the scheme. On the other

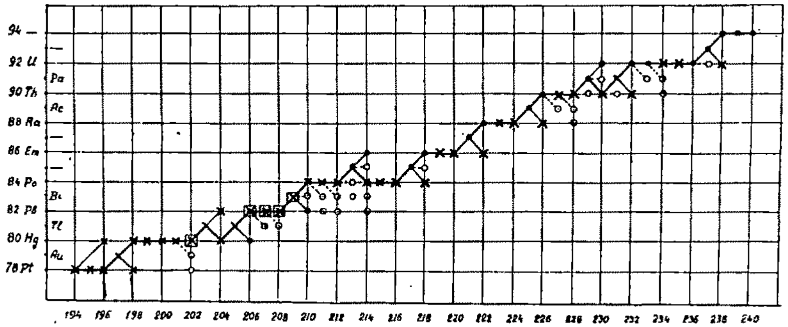

Fig. 1. SYSTEMATICS OF ISOTOPES.

✕ known stable and α-active isotopes.
● expected stable and α-active isotopes.
○ unstable, β-active isotopes.

hand, all nuclei which do not follow the scheme (1) are unstable, that is, β-active. For example, $^{40}_{19}$K is formed from $^{39}_{19}$K by addition of a neutron (instead of the expected addition of a proton); it does not follow the scheme and is therefore unstable. $^{40}_{19}$K, being transformed to the permitted configuration, $^{40}_{20}$Ca, emits β-rays (T approx. 10^8 years).

Artificially obtained $^{198}_{79}$Au likewise (see Fig. 1) is formed by the addition of a neutron, whereas after the first proton ($^{196}_{78}\text{Pt} + ^{1}_{1}p = ^{197}_{79}\text{Au}$) a second proton was to be expected. This nucleus is again unstable (β-active) and disintegrates with a period T of 2·7 days.

After the addition of the first proton, there are two possibilities of a further complication of nuclei: either a proton ($A = +1$; $Z = +1$) or an aproton ($A = +1$; $Z = -1$) may be added. As a result, two isobars with the same A, but differing in Z ($\Delta Z = 2$), may be formed in accordance with Mattauch's rule.

For example (see Fig. 1):

$$^{202}_{80}\text{Hg} + ^{1}_{1}p = ^{203}_{81}\text{Tl}; \quad \begin{cases} ^{203}_{81}\text{Tl} + ^{1}_{1}p = ^{204}_{82}\text{Pb}. \\ ^{203}_{81}\text{Tl} + ^{1}_{-1}a = ^{204}_{80}\text{Hg}. \end{cases} \qquad (2)$$

According to scheme (1) above for elements with Z greater than 7, after the addition of the first proton, either a second proton or an aproton, but not a neutron, must follow. The result is that elements with odd atomic numbers may have either *one* isotope, for example, $^{197}_{79}$Au, or, in the case of addition of an aproton, *two* isotopes, for example, $^{203}_{81}$Tl and $^{205}_{81}$Tl (Aston's rule).

The introduction of a new type of particle taking part in the formation of nuclei, namely, the aproton, may be justified also by the fact that new regularities in the nuclear properties may thus be discovered. For example, the addition of a proton or an aproton is followed by a spin change $\frac{3}{2}\hbar$, and the addition of a neutron by a change $\frac{1}{2}\hbar$; the addition of an aproton results in the disappearance of the electric quadruple moment of nuclei, for example, $^{69}_{31}$Ga, $^{75}_{33}$As, $^{115}_{79}$In, etc.; when the position of a nucleus falls in the (Z, A) graph between two stable isobars, with $\Delta Z = 2$, formed by addition of a proton and an aproton to the next isotope with lower mass, a branched ± β-activity is observed ($^{64}_{29}$Cu, $^{76}_{33}$As, $^{104}_{75}$Rh).

Following L. Turner[3], it may be interesting to make a suggestion (Fig. 1) concerning the genealogy of isotopes of heavy elements with the help of scheme 1 above.

All heavy elements may be arranged in five radioactive families, one of which is presented on Fig. 2. This family is especially remarkable because all its members, except the final product $^{209}_{83}$Bi, have vanished.

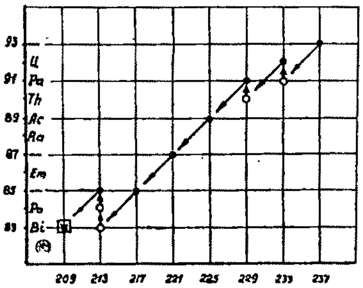

Fig. 2. EXTINCT RADIOACTIVE BISMUTH FAMILY.
X α-active isotopes.
O β-active isotopes.

Among the members of this family, the following isotopes of elements, according to Mendeléeff's table, should be found:

$$\begin{aligned} Z &= 85 \quad A = 213 \text{ and } 217; \\ Z &= 87 \quad A = 221; \\ Z &= 89 \quad A = 225. \end{aligned} \qquad (3)$$

As recently shown by Corson and Mackenzie[4], element $Z = 85$ can be obtained by bombardment of bismuth with α-particles. This is obviously the last element but one in the extinct bismuth family and it is α-active ($T = 7{\cdot}5$ h.). Both Paneth[5] and Mlle. Perey[6] have discovered α-activity in actinium ($Z = 89$) and supposed that $^{227}_{89}$Ac possesses besides β- also α-activity.

As may be gathered from Fig. 1, $^{227}_{89}$Ac cannot be a stable isotope and must therefore emit β-rays. At the same time, actinium must have another isotope, $^{225}_{89}$Ac (see Fig. 1), which is stable against β-decay (it follows scheme 1) and may show α-activity. This isotope must be another member of the extinct bismuth family.

LEO PONISOVSKY.

Role of Acetylcholine and Vitamin B_1 in Nervous Excitation

AT the cut end of a peripheral nerve acetylcholine[1] and vitamin B_1[2] are set free and diffuse into the bathing fluid at rest and during excitation. The amount set free during excitation is considerably greater than during rest. The production of these and maybe other substances at the cut end of a stimulated nerve can be made visible with the aid of the *Schlieren* method of Toepler[3]. If short periods of stimulation are interchanged with periods of rest, the substances diffusing out are seen as little outbursts of 'clouds' near the cut end of the nerve, showing that it is mainly the excited state which leads to the production of these substances. Their appearance might have been due to a decrease in permeability during excitation and not to an actual formation. This possibility is ruled out by the fact that freezing stimulated nerves with liquid air, making use of the principle of the Doppler effect in order to accumulate the excitation waves, leads to an actual increase of these substances in extracts obtained from the frozen and minced nerve. In the excited nerve (sciatic of Hungarian Esculenta) an increase of 0·1 μgm. acetylcholine per gm. nerve has been measured with great regularity in fifty independent experiments, with an average error of ± 0·01 μgm. The ratio of acetylcholine content in stimulated and unstimulated nerve is 1·6[4]. The extracts of stimulated nerves show at the same time a great increase in vitamin B_1 content. This increase has been demonstrated with six independent methods (increase of the response of a leech-preparation to acetylcholine[5], a new polarographic method[6], Flagellatæ-test[2], Phycomyces-test[7], bradycardia-test of the rat[8], thiochrome-reaction[9]) and amounts to 2 μgm. per gram nerve.

Incubation of nerve extracts[10], or of small nerve pieces[11], with oxygen and glucose leads to a formation of acetylcholine. The increase is larger in bound than in free acetylcholine[10]. Bringing these facts in relation to results obtained with brain-preparations[12], it is probable that the potassium ion has a direct influence on the equilibrium between bound and free acetylcholine in nerve and that the presence of pyruvate and vitamin B_1–co-carboxylase is necessary for the formation of an acetylcholine reserve upon which the nerve can draw in case of prolonged stimulation. If nerve preparations are treated with ferricyanide and alkali, according to a new histological technique[13], the fluorescence-microscope reveals that the thiochrome, formed from the vitamin B_1–co-carboxylase system in nerve, is located in the myelin-sheath. The axon shows practically no fluorescence due to thiochrome. Measurements of the repartition of co-carboxylase, determined by the method of Lohmann and Schuster in fibres of the squid, show an accumulation in the myelin-sheath, and cholinesterase seems to be located almost only in the sheath[14]. The myelin-sheath therefore must be regarded as a storage battery in which acetylcholine-formation from the phosphatide- and the glucose-pyruvate-breakdown take place. The decrease of insoluble phosphate and the increase of acid-soluble phosphate during excitation of peripheral nerve[15] points out that the phosphate set free with the liberation of choline from phosphatides is taken up by acceptor-systems like creatin, adenosin- or vitamin B_1, which play an important part in the maintenance of the resting potential of nerve[16].

Single nerve-fibre preparations are highly sensitive towards irradiation with *short*-wave ultra-violet[17]. Wave-lengths of more than 290 mμ have no effect at all. But if the ultra-violet light (all wave-lengths) is filtered through a quartz-cuvette containing vitamin B_1 there is also no effect at all. The change in excitability with irradiation is twofold. With small doses there is a regular and considerable decrease of the threshold. Larger doses lead to an irreversible effect with increase of threshold, loss of excitability and destruction. Vitamin B_1 is very sensitive to ultra-violet of less than 290 mμ with a maximum of photochemical decomposition at 255 mμ[18] (pH = 7). Tryptophane and other filters with different absorption properties have not the same protective action towards the photochemical action of light on preparations of single nerves. Although all nucleotides have similar absorption spectra[19] it seems that the photodynamic action of short ultra-violet on single nerve fibres is mainly due to photochemical decomposition of vitamin B_1 and is comparable with the changes in excitability connected with avitaminosis.

Vitamin B_1 as a phosphate donator and acceptor system with its co-carboxylase activity in the diphosphorylated state is an essential factor in the excitation process of peripheral nerve. Acetylcholine formation and mobilization of energy seems to be connected with co-carboxylase activity during or shortly following excitation. 'Recharging' must be the function of the system, and it is therefore not surprising that in polarization the vitamin B_1 content is increased near the anode[13] and that photochemical destruction or avitaminosis has the same effect as cathodic-polarization on excitability.

Full details will be presented elsewhere. I am indebted to the Rockefeller Foundation for grants in aid of this work.

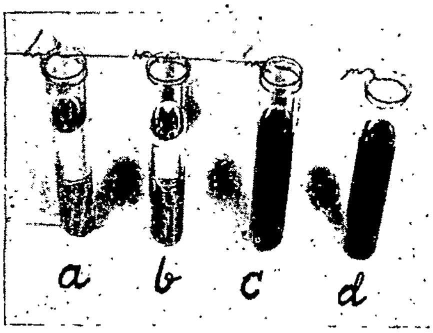
Promotion of the Corrosion of Iron in Alkaline Solutions by Zinc and Aluminium

THE preventive action of zinc on the corrosion of iron is well known and has been practically applied for a long time (galvanizing of iron). Also aluminium has been tried for the same purpose. In special cases, however, small amounts of zinc or aluminium may have a quite opposite action. For example, it has long been known that iron which has been passivated in strong nitric acid is activated by being touched with a piece of zinc, after which it is readily corroded. It has now been found that in certain alkaline solutions somewhat similar reactions may occur.

In two earlier communications I have published some facts about the passivity and corrosion of iron in strongly alkaline solutions in the presence of certain organic reagents[1]. By further experiments, partly with other reagents and sometimes extending over longer periods of time, the earlier observations were confirmed and completed. In many cases there was found a well-defined difference between passive and active iron in the same alkaline solution. With passive iron the attack is very slight, if any; the metal remains bright and does not give any coloration to the solution. Active iron corrodes more or less rapidly, its surface darkens and, in some cases, it causes a coloration of the solution. With special reagents this coloration is very intense and can be observed immediately after the activation of the metal. In this case the reagent may be considered as a kind of indicator (compare ref. 1). In other cases the first signs of corrosion are not found until several days or even weeks have passed. The change from the passive to the active state is affected by a cathodic action which causes a reduction of the protecting oxide layer on the iron. To produce this action only small amounts of zinc or aluminium need be in contact with the iron. When the less noble metal is later on removed or dissolved, the iron remains in the active state.

The experiments on which these statements are based were carried out in different ways. It was shown, for example, that a sample of pure iron nails covered with an alkaline reagent solution was preserved rather well during 1–2 months, whereas distinct signs of corrosion were found in the same solution if a few galvanized nails also were present. Another way of demonstrating the effect is shown by the accompanying figure. The reagent solution was 3·1 *N*. sodium hydroxide containing 3·6 gm. of nitrosoguanidine per litre. The test-pieces were soft, polished 0·8 mm. iron wire, spiral-wound. In *a* and *b* the spirals were wound round a glass rod, in *c* and *d* round a rough aluminium rod and abruptly pulled off. In the latter case small amounts of aluminium stuck on the iron and caused activation in the solution. The photograph was taken six hours after the beginning of the experiment.



In most cases the alkali used was sodium hydroxide in concentrations varying between 2 *N*. and 3·5 *N*. Among the reagents used may be mentioned dithio-oxamide, nitrosoguanidine (indicators), tartrate and citrate (no immediate change is observed). Self-activation may occur with dithio-oxamide. A few experiments even showed an effect in pure alkali without a reagent.

From what has been said above, it is obvious that the corrosion conditions of iron in alkaline solutions deserve further examination. More details of the experiments already made will be published later. The investigations will be continued should conditions permit.

The main part of this work was carried out at the Corrosion Laboratory of the late Prof. W. Palmer at the Nobel Institute, Stockholm.

Physiology of Colour Vision

ON Mr. Willmer's[1] theory of colour vision, three sets of nerve impulses reach the brain, one set from the rods only, another from the cones only (which on his theory are all alike) and another from the flat bipolar cells which connect together some of the rods and cones.

On this theory, since the flat bipolar cells are connected to rods and cones, the frequency of impulses, f_m, from the flat bipolar cells is dependent only on their constitution, and the frequencies, f_r and f_c, of the impulses from the rods and cones. Hence f_m is not an independent variable—there are only two independent variables, f_r and f_c.

Now the colour manifold of the normal individual, or *tri*chromat, is clearly *three* dimensional—colour sensations have the *three* independent qualities of colour, intensity and saturation—and therefore need *three* independent variables to represent them completely. It is for this reason that, for example, the Young-Helmholtz theory has *three* fundamental sensations, or, as another example, that every colour can be perfectly matched in all its qualities by means of a unique mixture of the light of *three* standard wave-lengths, or, as a last example, that Clerk Maxwell represented the colour manifold by a *three*-dimensional solid, the pyramid with the colour triangle as its base.

On Mr. Willmer's theory, which has only two independent variables, every conceivable colour sensation would have only two independent qualities, for example, colour and brightness or a combination of colour and saturation and a combination of saturation and brightness. This is obviously untrue. Also, on this theory, every conceivable colour could be matched in all its qualities against a mixture of suitable intensities of any two monochromatic lights. (The intensities of one or other of the monochromatic lights might, of course, be negative, that is, one or other of the monochromatic lights might have to be added to the colour which it was required to match.) This also is well known to be untrue, except in the case of the colour-blind. When Prof. Hartridge[2] in his criticism of Mr. Willmer's theory points out that a mixture of red and violet cannot produce every colour of the spectrum, he really is considering one particular case of the more general criticism outlined above.

[1] NATURE, **151**, 213 and 632 (1943).

[2] NATURE, **151**, 422 (1943).

ACCORDING to Mr. Willmer's original hypothesis, a simultaneous stimulation of the rod elements and cone elements produces the various shades of green, yellow and orange which are found in the visible spectrum. One of the difficulties of this theory is to explain the recognition of violet, mauve and purple, and the way these shades are differentiated from the above-mentioned spectrum colours. Mr. Willmer's recent hypothesis has been designed to overcome this and other difficulties of the previous one. According to this, strong stimulation of the rods and cones simultaneously causes an appreciation of green, yellow or orange, whereas the weak stimulation of the same receptors causes an appreciation of violet, mauve and crimson.

This modification of the hypothesis was tested in the following manner. Two colour filters were selected, one transmitting brilliant green and the other transmitting brilliant purple. Behind both were mounted a series of neutral tint gelatine films so that the intensity of light transmitted by both the above filters was reduced in intensity, the first step being 1/10 of the full transmission, the next 1/100, the next 1/1000 and so on. According to Mr. Willmer's theory, we should expect that the green filter would, if sufficiently decreased in intensity, change to purple or violet. Vice versa, we should expect from this theory that the purple light transmitted by the other filter would, if sufficiently increased in intensity, change in colour to green. On testing both these eductions experimentally neither was found to be he case. The green remained green at all intensities nd the same applied to the violet.

The above experiments do not fit in with Mr. Villmer's theory.

H. HARTRIDGE.

FOR many years it has been taught with more or ess dogma that colour vision depends upon three ypes of cones. In the mammalian retina no such ifferentiation of the cones has been made with any egree of certainty. It is true that there are some bservations which have been regarded as favouring uch a view, but there are just as many which can e used as arguments against it.

For this reason it seemed to be worth while to aise again the question as to whether in fact it is ot possible to explain colour vision in terms of the ctivities of rods and cones and their now more rmly established neural connexions. As an attempt 1 this direction the hypothesis somewhat inadequately utlined in two previous articles[1] suggested a possible asis for colour vision resting on the properties of ods and cones only. Essentially the hypothesis uggested that the ratio of the responses elicited from he rods and cones might determine the hue, some unction of their difference the saturation, and the bsolute frequency of the cone impulses, or perhaps ne sum of the rod and cone frequencies, might egister the intensity.

Prof. Hartridge[2], Dr. Craik[3] and Mr. Holbourn above) have all raised fundamentally the same bjection, and it would be idle to deny that it is an extremely serious one to the hypothesis in its present orm. Whether, on the other hand, it necessarily invalidates the hypothesis as a whole can only be judged fter it has been possible to review in more detail the rguments both for and against the hypothesis. uch a review is in course of preparation.

our Years of Planned Feeding in Great Britain

ONE paragraph in the article on the above subject[1] somewhat misleading. Dr. Pyke, discussing the rotein requirements of the human body, states that he normal consumption of bread and potatoes provides ufficient protein for bodily needs. Unfortunately, as r. Pyke is no doubt himself aware, the protein of read and potatoes (and of most cereals and pulses) , in itself, inadequate for the building of human rotein since it is deficient in some of the essential mino acids, notably tyrosine, lysine and tryptohane, which the human body is, of course, unable o synthesize.

June 30.

ALAN BLAINEY.

NATURE, 151, 658 (1943).

As Mr. Alan Blainey inferred, I purposely refrained from discussing the problem of requirements of first-class protein in my article.

The assessment of requirements of first-class protein is extremely difficult. While on one hand it would be dangerous for the national consumption of animal protein to fall to a figure lower than, say, 25 gm. daily, there is on the other hand a good deal of evidence that very much smaller amounts of animal protein when eaten mixed with protein of a lower biological value substantially raise the biological value of the whole. Thus, quite small amounts, say, of dried egg, mixed with large amounts of cereal protein in a made dish, would possess a biological value little lower than that of egg protein itself. Similarly, it has been found that the biological value of the protein in a complete mixed day's diet of a normal character is practically as high as the value of the first-class protein in it, which may make up only a small fraction of the total amount.

Besides the difficulties of making a scientific assessment of the requirements of animal protein needed per head of the population, there are the added difficulties of national prejudice. For example, men doing heavy muscular work feel that they have increased need for meat, although it has never been proved that muscular work increases the requirements of animal protein.

In my article I did not mean to assume that protein requirements could be met from vegetable foods alone. Although the national diet must inevitably be restricted in war-time, there is little likelihood that all sources of animal protein can ever become completely unavailable. It is true that the adequacy of supplies of first-class protein must be a matter for close scrutiny.

This matter, as I may have indicated here, was, in my opinion, too complex for discussion in the general type of article which was published in NATURE of June 12. Nevertheless, the fact remains that the increased use of foods such as potatoes and flour of high extraction in the national diet ensures an adequate proportion of *total* protein.

Future of Technical Colleges

THE letter by Messrs. Barrer and Andrews[1] from the Technical College, Bradford, will surely be as great and as distressing a surprise to many as it has been to me. The admirable work of technical colleges plays so great a part in the nation's welfare one would indeed hope they would stand proudly upright on their own feet rather than dissipate energies in screw-jacking themselves painfully to some self-determined level they choose to regard as of "university rank and status". Cannot they take heart and be persuaded to see themselves as others see them ? When I was with good colleagues during the War of 1914-18, in the Manchester College of Technology, we found it good and sufficient to be of a great institution. Many close friends who have worked or do work in technical colleges tell me, however, that an undue amount of energy is expended in preparing a very small nucleus of students for external degrees of a university, and thereby is diminished the potential for the dominant duties which the technical college has to perform : if this be so, it is a great pity. Therefore I was extremely glad to see Sir Lawrence Bragg's Committee of the Institute of Physics recommended that "it should not be a *primary* function of a technical college to educate students for External University Degrees".

All external examinations are abomination and an evil rot in an educational system. The extent of their evil is stated with masterly directness by A. N. Whitehead on pp. 7 and 8 of his essay "The Aims of Education", and I urge Messrs. Barrer and Andrews to read it. Surely all teachers will hail joyfully the statement from the Institute of Physics and use it as a heavy missile to hurl at that horrid monster, the external examination, and at all who nourish it.

The suggestion that the Committee's proposals deny "the right of the technical college to give the highest training to the young technologist" is a *non sequitur*. The young technologist will demand, and on the whole get, the highest training his instructors are capable of providing. Students realize they cannot explain to their teachers what good instruction consists of, but youthful eyes perceive unerringly what instruction is sincere and what is not.

We are told that "Even major technical colleges have suffered too much in the past from being maintained as subordinate institutions. From this position, the only means of escape has been to become university colleges, . . ." We are not told by whom they have been kept subordinate, and so painfully as to need escape. Section 333 of the Report on Education by the Bradford I.L.P. Commission states that "The universities, although their work is of vital importance to the community, lie a little outside the main current of modern life. They deal largely with specialist topics: they have grown up gradually and possess a vitality, a principle of development of their own". Accepting, then, this statement, it would seem that if major or even minor technical colleges have ever been so craven as to escape thus from "the main current of modern life", at least they happen to have found sanctuary where they can learn "a principle of development of their own", and some day may feel brave enough to return to the world and their duties.

Let us hope we shall hear no more of climbing ladders in a world of rank and status, ever fearful of being de-ranked, but devote all our thoughts to ascending the steady gradient in the kingdom of the mind, a task which brings peace and contentment to all men who will consistently lift up their eyes and look outwards.

Science, Christianity and Truth

Errors such as Dr. Huxley denounces in the first part of his letter[1] probably arise from the confusion of two distinct, and indeed contrary, doctrines. One is that moral values are as irrelevant to science as the rules of chess are to the sport of angling; the other is that science leads to the positive conclusion that moral 'values' are invalid. Each of these doctrines has been supported by some men of science especially among chemists and physicists; but, as Dr. Huxley says, specialists in evolution, which Mr. Hardwick considers to be the basis of his confused doctrine, have usually rejected both.

A few years ago, it seemed likely that religious apologists would adopt the first doctrine, and would therefore cease to write books about science and religion. Apparently they have had difficulty in persuading people that the study of facts, now everywhere recognized as essential to decisions about means, has no bearing upon ends. If that is their reason, those who are less rash than Mr. Hardwick will scarcely adopt the second doctrine. The only alternative open to them seems to be a return to natural theology, namely, the doctrine that science does throw light on metaphysics and ethics, and that this light is favourable to official Christianity. Some of them must surely be regretting that their grandfathers, in a panic about evolution, killed Paley so efficiently that not even the eloquence of an Eddington can revive him.

[1] Nature, 152, 79 (1943).

While I should like very much to agree with the point of view put forward by Dr. Julian Huxley in his letter[1] under the above title, I feel his attitude is almost as unscientific as that of the Rev. Hardwick whom he criticizes.

(1) Dr. Huxley must know that in the book[2] to which he refers strong arguments are given against the view that "evolution . . . provides the only external yardstick or standard by which to measure the correctness of our social principles and our ethical judgements". Yet in his letter he makes no attempt to refute such arguments, nor does he even refer to their existence.

(2) I agree that the second quotation which Dr. Huxley gives from the Rev. Hardwick's review need not worry men of science at all; but surely the first is not so extraordinary as Dr. Huxley supposes. There is as much disagreement among men of science, I think, about the best form of social organization as among non-scientists. There are many German and Italian men of science who are Nazis and Fascists, and there are many British and American men of science who are not Communists. If the ethics of society can be settled by an appeal to evolution, it would be interesting to know why such disagreement exists. The obvious explanation is that such disagreement is not a scientific one, but due to 'fads' or 'prejudices'. Dr. Huxley says that this is unscientific, but it seems to me to be unscientific of him to say so, unless a very good reason can be produced why so many men of science are acting unscientifically.

INVESTIGATIONS INTO SAL AND TEAK

INDIAN Forest Bulletin No. 115, Utilisation (For. Res. Inst. Dehra Dun, 1942), discusses a fascinating problem in connexion with many tropical timbers which has puzzled possibly generations of forest officers, to wit, how to distinguish between the sapwood and the heartwood. This title, with the addition of the words sal (*Shorea robusta*), is the subject of the bulletin. The author in charge of the wood technology section of the Institute sums up his investigations—it is not always safe to assume that the true sapwood and heartwood of sal can be distinguished merely by their colour. The best method is to find out whether tyloses are present or not in the pore cavities. When tyloses are present the timber is heartwood, and when absent, sapwood. The colour, whether pale reddish-brown or dark reddish-brown, is immaterial and no true indication.

In Bulletin No. 113, Utilisation (1942), from the Institute is an interim report on "The Relation between Rate of Growth and Strength of Natural and Plantation Teak". "How fast should trees be grown ?" inquires the author, and adds, "it is a question forest officers often have to ask themselves, and especially those in charge of plantations". Compared with India's vast forests her artificial plantations, important though they are in their several localities, are a mere grain of sand in the great whole. But this question needs consideration in India, and in tropical countries generally, just as much as it will be found to require careful study in Britain in connexion with the afforestation work of the Forestry Commission ; based as so much of it is on exotic conifers.

The author of the bulletin is merely repeating a forestry platitude when he says that the chief aim (one of the chief, he remarks) of most forest plantations grown for timber is to produce high-quality timber in the shortest possible time. Marketable timber, omitting the 'high quality', would be a truer definition of modern-day practice. The first plantation formed of teak under British action was the famous Nilumbur (or Conolly) Teak Plantation, the first compartment being planted in 1843. Such was the success of this fortunately and fortuitously situated plantation (on the Beypore river some forty-eight miles distant from Calicut, west coast of Madras) hat it has been copied elsewhere in India and Burma with varying success, and also in Africa and other parts of the tropical world. In many cases the young planted teak plants have shown an abnormally ast height growth in early years; in other words, the growth in a few years of a product which could ften find a ready market long before it came to timber size.

The problem which is discussed in the bulletin s the question of the effect of the rapid growth on the strength of the product produced, for there are obvious limits ; it is just the question of what the optimum rate of growth is for different species which emains an unknown factor. It is an accepted dictum that very fast or very slow (the latter with exceptions) grown timber is usually deficient in strength. On the subject of teak and the information gained, the author states that the existing data have been analysed and the record given in the bulletin. From the limited data available (in spite of the fact that t is just a century since Conolly commenced the formation of the Nilumbur plantation), says the author, "it will be seen that a rate of growth of about 5–6 rings per inch has been found to produce the strongest timber, and a rate of growth faster than about 4 rings per inch produces very weak timber". It is also added that plantation teak, although fast grown, is in no way inferior to natural teak so far as its strength properties are concerned. It is worth while mentioning that the warning is given that the data available are still insufficient, except "as an interesting indication" : and, it should be added, a dangerous one upon which to build up large plantations of rapid-growing exotics, wherever practised in the Empire.

THE BRITISH WAY

By LIEUT. T. H. HAWKINS

WAR makes strange situations; and no war can have thrown up a situation more strange than the one that the appearance of the Oxford Pamphlets on Home Affairs represents*. Instead of indulging their well-established habit of grousing at all things British, our fellow-countrymen are now learning to be not ashamed of expressing their deeper and more real feelings ; some of the bolder individuals are even talking with unconcealed pride of the traditions and institutions of Great Britain.

The publishers of these booklets have sensed this change in the national mood and have launched a series which should prove as useful and informative as the more familiar "Oxford Pamphlets on World Affairs". The new series has been prepared on lines similar to the World Affairs Pamphlets and offers short summaries of various sides of life and living in Great Britain. They bear striking resemblances to the series of booklets called "The British Way and Purpose" which have been issued monthly to all units of the British Army since last November and should get a reception as favourable as the latter have done with the troops.

(1) Mr. McCallum's book describes the institutions and methods by which Britain is governed, how parliamentary government has grown side by side with the monarchy, the relations between the Crown, Ministers, Parliament and people and how the party system works in effecting the will of the electors. But while men of Britain are intensely proud of their forms of government, they are only too conscious of the deficiencies. Mr. McCallum would have offered a greater contribution to the future of democratic government by discussing some of the defects of our governmental institutions and their possible remedies.

(2) The pamphlet written by the member of Parliament for Keighley is a miniature guide for the newspaper reader. It explains the difference between the various kinds of reading-matter in a newspaper ; the "sacred" facts and the "free" comment, "features" and advertisements. How the materials are collected from various sources is clearly set out, as is also the varying forms of newspaper ownership. Mr. Thomas then deals with some important problems such as the maintenance of journalistic standards, the control of newspapers for profit, power, or service, the influence of advertising and the power of the Press to influence public opinion.

---

* Oxford Pamphlets on Home Affairs. No. H(1): How Britain is Governed. By R. B. McCallum. Pp. 32. No. H(2): The Newspaper. By Ivor Thomas. Pp. 32. No. H(3): The Transition from War to Peace. By A. C. Pigou. Pp. 32. No. H(4): Britain's Future Population. By R. F. Harrod. Pp. 32. (London: Oxford University Press, 1943.) 6*d*. net each.

(3) Prof. Pigou's pamphlet deals with the more difficult subject of the post-war period. The following are some of the questions he poses : What is going to happen when war-time machinery is quickly reversed ? How will the transition back to peace-time production be effected ? Will those who were employed before the War get back to their old jobs ? Will those who have reached employable age during the War find jobs ? The author suggests answers to these and other problems mainly by drawing from the experiences gained during 1919–22. His essay will be of particular value to all those who are charged with conducting discussion groups in the Civil Defence Services and Armed Forces and will enable them to deal with some of the questions that are constantly being asked about the post-war period.

(4) "Britain's Future Population" discusses the tremendous problems that accompany a declining birth-rate. The method of presenting these problems leaves much to be desired, while the novel suggestions Mr. Harrod makes about the real causes of the fall of the birth-rate need fuller investigation.

In addition to the four pamphlets under review, preliminary announcements indicate that subjects to be dealt with in succeeding issues include the Civil Service, trade unions, the British political parties, education in Britain, law, money, agriculture, foreign trade, the problem of full employment and related topics.

RELIEF IN EUROPE AFTER THE WAR OF 1914-18

THE brief study on relief after the War of 1914–18, entitled "Relief Deliveries and Relief Loans, 1919–23", which has recently been issued by the Economic, Financial and Transit Department of the League of Nations, is one of a series devoted to a consideration of the lessons that may be learnt from past experience. It should prove of value in giving effect to the resolutions of the Food Conference at Hot Springs which, as Mr. Eden announced in the House of Commons on July 6, have now been accepted by the Government. Mr. Eden, in making this announcement, stated that the Government intends to press on with the task of increasing food resources and improving the diets of the people. It also intends to participate fully in the work of the Interim Commission to prepare a plan for a permanent organization in the field of food and agriculture. While the Conference was not concerned with the organization of relief supplies, attention was given to the need for increasing supplies of basic foodstuffs in the period when territories liberated from the enemy will be in need of help from outside, and Mr. Eden said that the Government is much impressed by the urgency and importance of this problem.

In reviewing the relief effort of 1919–23, it is pointed out that international relief on a scale comparable to what was required had never been previously undertaken. There was no past experience to serve as a guide, save that of the Commission for Relief in Belgium during the War of 1914–18. In regard to the volume and nature of relief, the report notes that although the child-feeding programme prevented a disastrous mortality, it was not adequate to prevent malnutrition. The real needs were never completely met, nor were they fully surveyed. Th were considered almost exclusively in terms of calori and the study concludes that the first action requir to meet such a situation with any hope of the be result is to estimate so far as possible in advan what the real needs of food (including protecti foods) and such essentials as soap, medicine and clot ing are likely to be and how far they can be met fro the available resources.

The War of 1914–18 ended in the autumn when th need was greatest, and the possibility of relying domestic supplies, except for cereals, was least. Th shipment and transhipment of goods to Europe w expeditiously carried out and great efforts were ma to effect actual deliveries with the least possib delay, but the continuation of local fighting and th breakdown of internal administrative organizati in many parts of Central and Eastern Europe, th absence of information regarding local needs, pa ticularly in these same areas, and the difficulti encountered in co-ordinating the relief efforts of th United States and the Allies, made impossible su stantial deliveries of foodstuffs, except in Belgiu and northern France, before the end of January 191 The major relief period was confined to February August 1919.

A further difficulty was the delay in obtaini legislative approval of relief credits ; this could ha been prevented if funds had been allocated duri the War. The stock situation in the United Stat was not such as to put difficulties in the way of larg scale export for relief purposes : the problem w rather to dispose of surplus. In the harvest ye 1918–19 the exportable surplus of foodstuffs was thr times as large as the pre-war annual exports. To-da the resources of available food consist not only of th stock of provisions at any moment of time, but al of the industrial equipment for preparing certa categories of protective foods in condensed form.

The study emphasizes once more that if th tonnage available is to be utilized to the best a vantage at a moment of extreme post-war urgenc a joint plan of allocation between the demands f the repatriation of troops, and transportation of foo stuffs, raw materials and other essentials requires be made in advance. As regards financial provisio in any policy of relief and reconstruction it is nece sary to decide first what sacrifice is to be made purely humanitarian grounds and what sacrifice it desirable to make to prevent social disturbances a to establish such order in war-affected areas as w permit the revival of economic activity. If adequa direct aid is not granted to render a country cred worthy, any subsequent scheme for reconstructi may break down and the credit granted under su a scheme prove unrecoverable. Relief and reco struction are two stages in an uninterrupted proce of transition, and the distinction between them determined not by the class of goods involved b by the conditions, or absence of conditions, for repa ment.

Once again the value of utilizing for relief adm istration the machinery which existed and o required expanding is emphasized, while the wit holding of relief credits from enemy countries is garded as a further illustration of the basic mista of failing to consider problems of reconstruction the outset. Finally, in considering what relief impl to any country granting it, it is necessary to consi not only the accountancy cost of the supplies th may be furnished, but also the real economic co

GRAPHICAL DETERMINATION OF ELECTRIC POWER CABLE RATINGS

A USEFUL practical study of this subject has recently been published by H. Waddicor (*J. Inst. Elec. Eng.*, 90, Pt. II, No. 15; June, 1943). The paper indicates the advantages of graphical methods for determining current-carrying capacities of power cables, and charts are described by which the ratings of three-core and single-core cables transmitting balanced three-phase loads can be obtained rapidly. The charts are applicable to cables laid direct in the ground or in air, and take into account the mutual heating effect of feeders laid in the same trench. Calculated and graphically determined values of rating are compared for a range of typical cases in order to exhibit the degree of accuracy obtainable.

In general, cable ratings are obtained by calculation from published rating tables, or by graphical methods. Individual calculations are precise but extremely tedious. Even with simplified methods of dealing with the various types of three-core cables, and the use of approximate formulæ for skin, proximity, sheath and armour losses, etc., the time involved is a serious item where many routine calculations have to be made. Their chief function is to enable accurate comparisons to be made between the carrying capacities of various types of cable laid under identical conditions. Tables of current ratings have been published by the British Electrical and Allied Industries Research Association, but have their limitations as they only give figures for cables for working voltages up to 22 kV., that is, for cables complying with B.S. 480–1933 and B.S. 608–1935. Graphical methods have the great advantages of flexibility and rapidity in use. In the design of the charts described in the paper, slight approximations are employed to maintain a balance between comprehensiveness and simplicity of operation, but the errors over the practical range are very small, and accuracy higher than is given by the tables is usually possible when dealing with non-standard conditions.

Variations between graphical and calculated values are caused by errors intrinsic to the chart design and those due to inaccurate plotting. The former are always small and the latter practically can be eliminated by large-scale charts; those used by the author measure approximately 48 cm. × 35 cm. In order to form some idea of the overall accuracy of the charts, a comprehensive range of cases has been taken and the ratings determined both by calculation and graphically. The results are given in the paper, which show that the maximum error involved is less than 2 per cent, the actual limits being $-1\cdot2$ per cent and $+1\cdot9$ per cent. Ratings can be derived from the charts in five minutes; calculation would require well over an hour.

The advantages claimed for the charts employed are that graphical methods of determining cable ratings are rapid and flexible; their overall accuracy is high, and they can be operated efficiently by personnel unacquainted with theoretical principles and methods; they are more comprehensive than the published rating tables, and for cables buried direct in the ground give more accurate results when applied to the diverse conditions of installation met with in actual practice; and graphical methods allow the effect of changes in ambient temperature, soil resistivity, depth of laying, or other factors affecting the cable rating, to be more clearly visualized.

RURAL ECONOMY IN YUNNAN

EVEN long years of war and retreat into the mountains have not stopped research of great social value carried out with a sympathy and fairness to non-Chinese folk that are altogether admirable. Yunnan's high rugged surfaces are cut by deep valleys; mountains tower above small upland plains; clans on the hills may long remain very separate from Chinese groups that have colonized the valley bottoms here and there; the hills may be sub-arctic at times, the valley bottoms may be almost tropical. Three authors have monographed Weits'un, where linger remnants of an almost feudal scheme, Luts'un, a village essentially of smallholders, and Yits'un, where poor cultivation is supplemented by crafts*.

In 1380 the Chinese occupied Weits'un and the native Lolos retired to the hills. In 1467 the Chinese resident, Hsu, took over all authority from the Lolo chief, and his house long retained overlordship, living in a town and collecting dues, but in the seventeenth century some came to live in the village and later enclosed and irrigated land in order to exact higher rent from it. Many of these Chinese landlords were killed in a revolt during 1847–72. The later settlement reinstated some Chinese but allowed the Lolos the right to buy land. Before the seventeenth century enclosures the forty-two tenants or allottees had been able to add to their lands, by digging up unused patches, without increasing their dues, which came to 1–3·3 per cent of the produce. In Hsu's time, fifty households with 270 people made up the village; in the seventeenth century there were ninety households with 530 people. Since the enclosures growth has been slow and there were, in 1939, 117 households with 637 people. Lolo land-hunger is a master passion, but there is little chance of gaining the wherewithal to buy. Chinese owners may lead idle lives for a while, but it is difficult for them to hold land worked for them by Lolos or to collect enough rent. Tenants may be begged to pay rent in advance, even to such an extent as to give these the right to seize the property; owners dare not refuse the request, and tenants often get into money-lenders' hands in the process. So they sink into poverty, and land tends to concentrate in a few hands, chiefly of moneylenders. The tenants try, with poor results, to keep afloat financially by seeking supplementary seasonal landwork in adjacent villages.

In Luts'un, 611 individuals live, for the most part, on the produce of 140 acres of rather good rice land. A family spends nearly half its income on rice and one eighth on other food. The village eats three thousand and produces nine thousand bushels. The largest holding is less than four acres, and only eighteen are of any size; thirty-eight out of 122 households are those of landless labourers. For a Chinese owner to save 'face' by living idle and employing Lolo labour he must have about two acres. Clans, clubs, temples, the village itself, the Water Regulation Association and the Government all own land, a good deal of which is let out at low rents, with some corrupt practice. An owner in debt tries to sell to his clan. Private purchasers have to obtain the consent of the seller's kin to the bargain. Sons divide the paternal inheritance. All in all it is just possible, here, to maintain a low standard of living.

* Three Types of Rural Economy in Yunnan. By Li-Yu-I, Hsiao-tung Fei and Tse-yi-Chang. Published in mimeograph. (Yenching-Yunnan Station for Sociological Research, January 1943.)

Yits'un supplements poor cultivation by basketwork on handicraft lines, with small but quick turnover, and by paper making, a process taking a year and making capital necessary. Paper mills rarely work all round the year for lack of bamboos, and they, like the land, are divided in inheritance. Investment in the poor land rarely pays, so profits from paper go elsewhere.

All in all, the lowly folk find advance almost blocked in every case and every direction unless one or two of them can become government officials and then use opportunities to enrich themselves and their families. One can but hope that efficient co-operative systems under schemes of public ownership may help these peasants. It is hoped that this interesting study may be made available in published form in England before long. H. J. Fleure.

ECOLOGICAL PRINCIPLES IN FORESTRY PRACTICE

At the invitation of the British Ecological Society, members of the forestry associations of Great Britain met on July 2 to discuss with the Society problems arising from a recent article by Sir Roy Robinson in *Forestry*. Prof. A. G. Tansley, opening the session, argued that the hypotheses of the "silvicultural stream" and of "accelerated succession" are based on ecological theories of succession, mixed plantings of pioneers and successors comparing with natural "telescoped" succession. He indicated the mutual benefits of still closer co-operation between foresters and ecologists, especially in investigations of the effects of pioneers on successors and of the autecology of exotic conifers. He also pleaded for due consideration by the Forestry Commission of the needs of nature conservation, particularly in view of the envisaged expansion of the Commission's programme after the War.

Sir Roy Robinson welcomed fullest co-operation from ecologists, the more especially because afforestation policy must be based on sound ecological principles. He indicated, among other pressing problems, those of soil relations, mixed plantations, and regeneration by means other than clear felling and planting. Prof. H. G. Champion instanced, from India, the ecological effects of soils and climates in determining the status of timber trees and the nature of climax and pre-climax complexes. He also discussed the importance of factors operating at comparatively long intervals, such as excessive drought and frost. Stressing the complexity of sylvicultural streams, he pointed out that afforestation may sometimes need to run counter to their currents. Dr. A. S. Watt stated the need for a dynamic conception of forest ecology. The pattern of the forest plantation must be determined by a variety of causes: microclimates, soils, relations between one plant and another, and the structure of the vegetation; the organic factors of the environment being no less important than the inorganic.

Discussion afterwards ranged widely over problems such as the status of afforestation programmes in national planning of land utilization and the construction of an ecological survey map of the British Isles; the function of shade bearers in controlling ground vegetation; the relative importance of surface vegetation and soil profile as a guide to planting; the functions of leaf litter, and of mycorrhiza and sub-shrub vegetation in regeneration; mixed planting and control of disease; the role of the smaller animals in the forest balance; and the need for preservation of samples of broad-leaved forest (*a*) for ecological study and advice in future programmes, and (*b*) as a part of the systematist's laboratory.

Sir Roy, replying to the discussion, reiterated his welcome of co-operation from ecologists, and stated that the Forestry Commission's ecological reserves would be re-established after the War, and that it is important to nominate now those woods desirable for such purposes, in view of the vast felling programme now in operation. L. A. Harvey.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

SPEECH THERAPIST (part-time)—The Education Secretary, Town Hall, Reigate, Surrey (August 20).

LECTURER (TEMPORARY) IN CHEMISTRY—The Registrar, University College, Southampton (August 25).

PROFESSOR OF PHYSIOLOGY, A SENIOR LECTURER IN ANATOMY, and A SENIOR LECTURER IN PHYSIOLOGY, in the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (August 31).

CHEMIST AND ASSAYER on the establishment of the South African Mint, Pretoria—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, London, W.C.2 (August 31).

HEADS OF THE DEPARTMENTS OF PHYSIOLOGY, MEDICINE, AND SURGERY—The Bursar, Royal Veterinary College and Hospital, at The University, Reading (October 1).

CHAIR OF NAVAL ARCHITECTURE—The Acting Secretary of University Court, The University, Glasgow (October 4).

ASSISTANT TO THE ADVISORY CHEMIST—The Secretary, South-Eastern Agricultural College, Wye, Ashford, Kent.

ASSISTANT (MALE OR FEMALE, preferably with a knowledge of Bacteriology and Chemistry) for Laboratory—The Pathologist, Cumberland Infirmary, Carlisle.

TEACHER (MAN OR WOMAN) OF MATHEMATICS, MECHANICS AND ELEMENTARY SCIENCE—The Principal, Erith Technical College, Belvedere, Kent.

FORESTRY EDUCATION

EDUCATION has often proved a thorny subject in Great Britain and is now again under very active consideration. But perhaps in no other branch has such a conflict of opinion existed and, it may be suggested, such a confusion of ideas combined with ignorance, as in the case of the training of the forester for the gazetted grades of the Government services. The subject first made its appearance in Great Britain after the institution of the India Forest Service in 1864. The late Sir Dietrich Brandis, first Inspector General of Forests in India, advised the Secretary of State of the necessity of providing trained probationers for the newly formed service. In the absence of any centre in Britain, the first selected men obtained their technical training at the forestry schools in Germany and France. This persisted until the inauguration of a forestry branch at the Royal India Engineering College of Coopers Hill in 1885. The late Sir William Schlich, who had succeeded Brandis as inspector general, was appointed professor, and the India forest probationers received their education at the College until it was closed down in 1905. On the subject of forestry, the Coopers Hill Committee, which in 1903 recommended the closing of the College as an educational establishment for training engineers for the public service in India, advised as follows:

> "As there is no efficient teaching of Forestry in the United Kingdom it will be necessary for some years to come that the Government of India should continue to provide for the education of the selected candidates. The Professor of Forestry and one of his Assistants must be maintained as heretofore. The question thus arises—where, in the absence of Coopers Hill, are Forest Officers to be trained? Although the average number of Forest Officers required by the Government of India will be only eight annually [a number which in actual fact was usually exceeded] the Government of India is too deeply interested in the matter to allow of its being left to chance, or to the future establishment of schools for instruction in Forestry in accordance with the recommendations of the Departmental Committee which reported to the Board of Agriculture. We think that it is possible, without much difficulty, to arrange for the transfer of the Professor of Forestry and even of his Assistant, from Coopers Hill to Cambridge or Oxford or Edinburgh. At the last-named University there is already the foundation of a Forest School [a lectureship in forestry was established in 1887]. . . . On the understanding that the pay of the Professor and his Assistant is provided by the Government of India, that Government should have a controlling voice in the choice of a Professor and in prescribing the course of instruction to be followed. Hereafter, when Schools of Forestry with suitable staffs and sufficient equipment shall have been established with success, their degrees or diplomas may be accepted as proof of sufficient technical training, and the selection may be made from those who have acquired those degrees and diplomas, and are otherwise well qualified. When this condition has been reached, the Government of India need no longer concern themselves with the teaching staff or the course of instruction."*

The above represents the reasoned opinion of the representatives of one of the Departments of State (the only one) who had before them at the time forty years experience of the working of the Indian Forest Department and its officers. Schlich decided upon Oxford, and the Secretary of State for India made a grant to the University.

The position of affairs was soon regarded as unsatisfactory both by the Government of India and the Secretary of State. A committee was appointed in 1908 to inquire into the selection and training of probationers for the Forest Service, consisting of Mr. R. C. Munro Fergusson (later Lord Novar), Sir John Edge, Sir W. Thiselton-Dyer, Mr. (later Sir) E. Stafford Howard, commissioner of woods and forests, and Mr. (later Sir) S. Eardley Wilmot, inspector general of forests, Government of India. In its recommendations the Committee said:

> "The advantages of a healthy competition between various Forestry Schools outweigh in our minds the benefits of a centralised training. Recognising, therefore, the importance of encouraging Indian Forestry education at other centres, and considering that giving a monopoly to any one centre must tend to discourage other centres from developing an adequate course, we recommend that a Professor of Forestry with an Indian experience be provided for centres such for example as Cambridge and Edinburgh as soon as the authorities of such centres have satisfied the Secretary of State in Council that a proper equipment for teaching forestry is provided at those Universities, and that their forestry courses will be open, as the Oxford course is at present, to any selected probationers."

The recommendation to provide a professor proved unnecessary. The Universities of Cambridge and Edinburgh, with the expressed opinions of these two Committees before them, set to work to fulfil the request. Cambridge had appointed a lecturer in forestry in 1907. Edinburgh inaugurated a degree of B.Sc. in forestry in 1909, and both built up forestry departments. In 1910 both Universities were recognized as qualified to train probationers for the India Forest Service. By this time the Colonial Office had also come into this market. Since that date, both the University of Aberdeen and the University College of North Wales, Bangor, have established forestry departments.

The old idea that one centre of training in Britain would suffice to supply all the recruits likely to be required for the India and Colonial Forest Services had not died, and periodically raised its head. But the universities were not greatly perturbed. They realized that competition, especially in educational matters, was the life-blood of the business; that a localized and centralized education of whatever type became inevitably parochial in its outlook and teaching. If this is true for more general forms of education, it is certainly so in the case of forestry.

This matter has come to the fore again in two separate forms. In *Australian Forestry* (6, No. 2; 1942), under the title "Higher Forestry Education", details are given of a controversy which has arisen between the State of Victoria and the University of Melbourne and the Institute of Foresters (whic publishes *Australian Forestry*). The Institute suppor the Australian Forestry School of the Commonwealt Government situated at Canberra and established 1926 with the sanction and support of all the State The State of Victoria no longer finds that th centralized school fulfils its requirements, and pr poses to set up its school in the University.

All the arguments used in this article (which is Report to Council by the past-president of t Institute) are old ones which have been voiced Great Britain and in India during half a century an more, and more latterly perhaps in connexion wi the British Colonies. The Institute's attitude summed up as follows:

> "The Institute deplores the violation of t principle of one national school for higher forest education in Australia. It makes an urgent appe to all persons interested in the progress of forestr in this country to support its action in condemnin this ill-conceived proposal."

The council of the University of Melbourne w not, however, to be deflected from its purpose. T Registrar pointed out that the action of the Universit was the natural result of twelve years experience the arrangements entered into in 1929, and he ga the reasons. The Premier of Victoria, in replying t the president of the Institute of Foresters, pointed o that:

> "The training of Staff for State Forest Service a matter regarding which Victorian Governmen have had thirty-two years experience. It has teste all the facilities for such training which have offere and considers that its own Victorian school, esta lished in 1910, and actually pre-dating both t Adelaide and Canberra establishments, most ad quately meets its requirements from the standpoi of Staff training. That it has now been decided th graduates from this school, who take their cour in association with Melbourne University, shall granted a degree in Forestry, seems both a logic and reasonable development, and one, moreove which should in no way disturb the existing positi as regards forestry education in Australia."

In Great Britain, on several occasions since t War of 1914–18, forestry education at the universiti has been under fire from Government department and from the Forestry Commission.

It has proved difficult, however, to obtain consensus of opinion as to what is considered to actually wrong. There appears to be some idea th the young university graduate should receive a f training as a woodman; or that the practical cours are not lengthy enough or sufficiently detailed; again, that the course should be a four-year o instead of three. There is usually a widespread failu to appreciate the fact that, at a university, forest is only one part of the varied curriculum which t undergraduate has to undertake, and that the vario courses are dovetailed with those of a number other departments. Why the so-called higher forest education should be considered as something exce tional and apart from other forms of training difficult to understand; for other courses of education at a university, if successfully undertaken, offer far higher emoluments in a subsequent career than a forestry service ever does.

Then again, an idea appears to persist that a forestry training should be carried out on the lines of an agricultural one. There is no similarity in the work. Government agricultural officers either engage in research or in purely advisory work, or are in charge of experimental stations with grants-in-aid to show improved methods of farming. The forest officer, on the other hand, has often charge of large areas of forest which, apart from their indirect benefits to the country, he is expected to make pay for themselves.

As a result of the War, there appears to be a probability that the Forestry Commission in Great Britain will increase its activities considerably. In such an event, it has already become obvious that the Commission will require to recruit a number of trained young men annually to its gazetted grades. This will, not improbably, apply to other Government forest services in the British Empire. Where are these trained men to come from?

Administrative circles concerned with forestry are in danger of repeating the mistakes of the War of 1914–18. During that period, recruiting for the forest services of the British Empire ceased. After the armistice of 1918, there was a great demand for young trained forest officers to fill the depleted ranks of the gazetted services. Large numbers of probationers were selected and sent to the universities to be trained. The latter, to grapple with the unprecedented situation, instituted shortened courses, doubling up some courses, giving shortened ones in others, and omitting a few. The results, as seen in forestry events of the past twenty years, have been by no means satisfactory, and in some cases even disastrous. In spite of this lesson and of warnings intimated during the present War, a not dissimilar position has once again to be faced—with the addition of the home forest service and its projected great increase in activities and demands for trained officers. Past experience shows the inadequacy of seriously shortened university courses. Given that the actual room exists to train a considerably increased number of candidates, the university forestry departments could train the necessary number of recruits within a reasonable period of time—but it must be pointed out emphatically that a training in forestry includes, apart from the science subjects proper, courses in applied science involving laboratory work such as, for example, forest botany, mycology, chemistry, entomology, and that room for larger classes attending these courses must also be available.

In other words, the various Governments of the British Empire, instead of criticizing and demanding much shortened courses in order to be able to start off at once on newly conceived and enlarged work, should realize that the universities of Great Britain, as a result of thirty years experience, are fully cognizant with the requirements of the training of the forest officer; that they know where their part of this work ends, and that of the officers of the Government departments concerned commences. For the newly joined young assistant conservator of forests has of necessity to be initiated in the particular methods of administration in favour in the country in which he is to serve, and often to study the habits and laws, and perhaps language, of the people among whom he is to serve. It will be obvious to all acquainted with university education and administration that such subjects and matters do not fall within a university curriculum which aims at giving the forestry aspirant a sound first degree in forestry.

AMERICAN EXCAVATIONS AT THEBES

Excavations at Deir el Baḥri, 1911–1931

By H. E. Winlock. Pp. x+235+96 plates. (New York: The Macmillan Company, 1942.) 30*s*. net.

THE site of Dêr el-Baḥri, on the opposite side of the Nile to Luxor, is familiar to all tourists in Egypt, for on it stands the most beautiful temple surviving from ancient Egypt, built in the Eighteenth Dynasty by Queen Ḥatshepsut. This temple and the adjoining Eleventh Dynasty one of King Nebhepetrē‘ Mentuḥotpe were excavated on behalf of the Egypt Exploration Fund between 1893 and 1907, and the results of this work were published in a series of memoirs familiar to all Egyptologists.

The possibilities of the site, however, were not yet exhausted, and in 1911 an expedition of the Metropolitan Museum of Art, New York, under the direction of Mr. H. E. Winlock, was granted the concession. For a generation—apart from the interruption due to the War of 1914–18—the New York party remained in possession, and work continued season by season, not only on the temples already largely excavated, but also on the adjacent tombs of notables, not to mention the early Christian monastery of Epiphanius close at hand and the palace of Amenophis III a short distance to the south. Every year when the digging season was ended and the expedition had returned home for the summer, a brief account of the season's work and discoveries was published as a special number of the Museum's *Bulletin*, and these annual reports, with a very considerable selection of their photographic illustrations, have now been garnered into the volume under notice, thus providing a consecutive narrative of twenty years digging which makes very interesting and at times entertaining reading, while the ninety-six plates collected at the end are admirable, and indeed contribute very materially to the value of this book to the student.

It is impossible in a short review to do more than indicate the most important results achieved by the excavators. In the Eleventh Dynasty temple of King Mentuḥotpe the original ground-plan of the temple courtyard was discovered, a plan that was considerably modified before the temple was completed. They also cleared the processional causeway leading up to the temple, as well as the adjacent causeway of Tuthmōsis III of the Eighteenth Dynasty, which led to the chapel of Ḥatḥōr cut into the cliff cheek-by-jowl with the earlier temple. But most interesting and important of all was the discovery within the temple itself of the burial-places of a Queen ‘Ashayet and of a little girl Mayet (‘the Cat’) which the previous excavators had missed. The burial of ‘Ashayet had been robbed and her mummy ripped open in the search for treasure, but her wooden coffin and stone sarcophagus—the latter sculptured without and painted within—were intact. The other burial was intact, but the uninscribed sarcophagus contained only the body of a little girl of five buried in second-hand coffins. The tombs of Mentuḥotpe's officials in the cliffs adjoining yielded the marvellous wooden models portraying life on the estate of the Chancellor Meketrē‘, the untouched burial of his steward Waḥ, and part of the correspondence of a land-owner named Ḥekanakhte, from one of whose letters we gather that famine was so sore in the land that in at least one village the people were reduced to cannibalism. In yet another tomb were found an embalmer's table and jars, while a quite unexpected discovery was a common burial of about sixty soldiers who had been killed in action, apparently during the civil war which resulted in the establishment of the rule of the Theban Mentuḥotpes over all Egypt.

As regards the temple of Queen Ḥatshepsut, the principal result was the recovery of innumerable fragments of the queen's statues and sphinxes which had been thrown out of the temple and destroyed by the order of Tuthmosis III, and the reconstruction of a number of them from these fragments. Another important discovery was a second tomb of Senmut, unfinished, but with a remarkable astronomical ceiling. Incidentally, on pp. 143 ff. the author gives a much more reasonable account of 'the Feud of the Thutmosids' than that invented by Sethe and accepted by Breasted. Another interesting discovery was the burial of Meryetamūn, daughter of Tuthmosis III and consort of Amenophis II, whose tomb has since received full publication, while yet another find was a tomb containing the bodies of three princesses of the Twenty-first Theban Dynasty.

There is much more of interest in this book than there is space to mention here, and it will make a welcome addition to the student's library. But with all its interest, it remains but a preliminary report. No excavation is justified which does not end in detailed publication of the finds, and it is earnestly to be hoped, for the sake of the advancement of knowledge, that the Museum authorities will endeavour to ensure publication of their wonderful material as speedily as circumstances permit, and so make it accessible to Egyptologists everywhere. Everyone will have his own choice, but the present reviewer would like to see precedence given to the tomb of ‘Ashayet, the burial of Waḥ, and the Ḥekanakhte correspondence, each of which in its own way is of outstanding importance.

As regards the book itself, there is much to praise and little to criticize. It is of convenient size, clearly printed, and, as already remarked, the plates are admirable. It is also going to save the researcher much time and trouble to have all these annual reports conveniently under his hand instead of their being scattered through the files of a possibly inaccessible periodical. A couple of tiny slips have crept in: on p. 79, l. 21, for pl. 45 read pl. 44; on p. 138, l. 3 from bottom, for pl. 65 read pl. 63. The kings' names Amen-ḥotpe, Thut-mose, are rendered thus instead of in the classical forms Amenophis, Tuthmosis, preferred by English scholars; this is only a matter of taste, but I fail to understand why S‘en-Wosret always has the diacritical mark following the Ṣ; there is no ‘*ayin* in this name.

R. O. FAULKNER.

BASES OF PHYSICAL CHEMISTRY

A Treatise on Physical Chemistry

A Co-operative Effort by a Group of Physical Chemists. Third Edition. In Five Vols. Vol. 1: Atomistics and Thermodynamics. Edited by Prof. Hugh S. Taylor and Prof. Samuel Glasstone. Pp. vii+679. (London: Macmillan and Co., Ltd., 1942.) 42*s*. net.

THE volume under review is the first volume of the new and expanded (third) edition of "A Treatise on Physical Chemistry", first published in 1924. The new edition is intended to provide an up-to-date and comprehensive review of the whole of physical chemistry in five volumes covering, respectively, atomistics and thermodynamics, the states of matter, chemical equilibrium, chemical kinetics, and, finally, molecular structure. It will be seen from this programme that the subject-matter is very comprehensive. The editors may clearly so interpret such a programme that it may embrace, without causing surprise, the whole of molecular physics and chemistry in all their ramifications, including, for example, some branches of these subjects which are not commonly thought of as physical chemistry or chemical physics.

The border-line between molecular physics and chemistry has become so indefinite that it would be wrong for any reader to criticize the editors and authors for their choice of included subjects, provided these come under the general heading of the properties of matter, with perhaps the proviso that the molecular structure of the matter in question is relevant. These considerations of scope are of immediate importance to the reader, for they will occur to him on reading the first chapter of the first volume, when he is plunged into consideration of nuclear structure, from the study of which, as a physical chemist, he may have felt himself mercifully relieved. A little further reflection, however, will convince him that the whole subject of stable and unstable isotopes, particularly of the common elements, and their separation and use, is essentially a branch of physical chemistry. Some methods of isotope separation, in fact, might be regarded as perfect examples of physical chemistry as distinct from physics or chemistry. Realizing this, and that a knowledge of nuclear structural varieties is naturally of interest to the user of isotopes, he will pull himself together and eagerly accept this expansion of his subject.

The volume under review is rather by way of an introductory volume to the whole treatise. It may be described as "Prolegomena to the Study of the Properties of Matter, for which its Molecular Structure is Relevant". The proviso is still of some importance. There are some properties of matter, studied, for example, in elasticity and fluid dynamics, in which the molecular structure can still sometimes be tacitly ignored. But even here signs are not lacking that this ignoration will not for long persist, and the deeper study of the properties of matter will soon proceed in all branches with explicit reference to its molecular structure and the properties of atoms and molecules. According to this interpretation of the programme of the treatise under review, any study of the properties of matter will then be a branch of physical chemistry, and none the worse for that! Future editors of this "Treatise of Physical Chemistry" may then arrange that it embraces an even wider scope. They will (or may) include sections, or rather volumes, on aerofoil theory and plastic flow in metals as part of one unified whole, "The Properties of Matter". This, however, is looking forward into the future. It may be possible and convenient when that time comes so to redefine physical chemistry as to retain for it a somewhat more limited scope, not greatly different from the present.

We must now return to this actual volume on atomistics and thermodynamics, and describe what it actually contains, with comments on the manner of treatment of the various themes. But it should be clear after these preliminary remarks that what the reviewer or reader must not do is to say of any section: "This is not physical chemistry, and should not be included".

This introductory volume consists of four chapters which are each of the nature of a more or less exhaustive monograph on their respective fields.

Chapter 1, entitled the "Atomic Concept of Matter", is by Prof. H. S. Taylor himself. No doubt with the view of emphasizing the importance of isotopes to the physical chemist, it is strongly nuclear in flavour, and might also be regarded as a short introductory survey of nuclear physics leading up to the necessary tables of isotopic varieties, stable and unstable (Tables XV and XVI). Short descriptive accounts are given of the various forms of precision mass-spectrographs in effective use, and also of the methods employed for the separation of isotopes in bulk. The account given of Clusius' important method of separation by a combination of thermal diffusion and convection will be found particularly valuable.

This monograph is then to be regarded as a general introduction to the atomic concept of matter, with special reference to the existence and separation of isotopes. Many matters are naturally touched on rather lightly in passing, of which, not being specially concerned with isotopes, the account given cannot do more than whet the appetite of the reader who is otherwise uninstructed. This, of course, is unavoidable in such a book. Chapter 1 cannot reasonably be expected to stand as an authoritative text on nuclear physics.

Some minor criticisms of detail may be made. It seems a pity that the periodic table of the elements is not given in the up-to-date form which logically follows from Bohr's theory, with the inert gases closing the various periods. The older form given on p. 8 is perfectly in order where it appears in this chemical introduction, but it should be supplemented later in the chapter by a modern version. Again, this chapter gives rise to a feeling that too much valuable space has been devoted to discussion of the precision values of the fundamental physical constants. Any such discussion to be of real value must be much more elaborate. This being rightly not attempted, a categorical statement should be made of the values to be adopted in this treatise. There is no useful half-way house. Finally, an incautious statement on the absorption of β-rays on p. 35, implying also that they possess no "range" in a stopping material, needs attention. Reference, for example, to Rutherford, Chadwick and Ellis, "Radiations from Radioactive Substances", shows that the effect is an extremely complicated mixture of scattering and energy loss, and any categorical statement such as that referred to is extremely misleading.

Chapter 2 consists of a substantial monograph on the quantum theory of atomic spectra and atomic structure by Dr. Saul Dushman. That the quantum theory is part of the necessary prolegomena to a deep study of physical chemistry cannot for a moment be questioned, but it must be asked what is the special feature of Dushman's treatment which makes it specially suitable as a text for study by physical chemists. Should they be advised to learn their quantum theory from this monograph or to use it preferentially as a handbook of reference? Various other texts on the quantum theory spring to mind as possible competitors—among others, Ruark and Urey's "Atoms, Molecules and Quanta", White's "Introduction to Atomic Spectra", Condon and Shortley's "Theory of Atomic Spectra", Frenkel's "Wave Mechanics" and Kemble's "Fundamental Principles of Quantum Mechanics", besides Dirac's "Quantum Mechanics" or Sommerfeld's "Atombau und Spektrallinien". But on reflection it must be admitted that for one reason or another none of these is quite fitted for the precise needs of the physical chemist. A specially adapted text is called for, and this Dushman sets out to provide on a plan which lays special emphasis on the experimental information on which the accepted views of the structure of the atom are based, and avoids so far as possible all appeal to any but the simplest mathematical aspects of the theory. As a result of his plan, the treatment may be thought to refer rather more to certain early stages in the development of the theory which are now largely of historical interest, such as Sommerfeld's treatment of the relativity doublet. It is, however, a matter of great difficulty in such an exposition to strike the correct balance between a too historical and a too abstract and *a priori* presentation. It may be agreed that Dushman has followed the middle way very successfully and in a manner well adapted to his purpose, though naturally individual tastes will differ from him here and there on matters of detail. The chapter forms an eminently suitable introduction or refresher course for a physical chemist, especially if supplemented by some more abstract treatment later on.

Chapters 3 and 4 are not so easily separable, and really constitute a single monograph on thermodynamics, with special attention to the use of thermodynamic functions constructed by the methods of statistical mechanics. Chapter 3, on the First and Second Laws, is again by Prof. H. S. Taylor himself. Chapter 4, on the Third Law of Thermodynamics and the use of the methods of statistical mechanics, is by Prof. J. G. Aston. Thermodynamics and statistical mechanics are together the keystone of any treatise on physical chemistry, and the value of this treatise must depend on the virtues of these chapters in a much more direct way than on the other two monographs, important as these are. The exposition of thermodynamics and statistical mechanics that they contain can be considered from two points of view: first, that of the instructed user who has already learnt the fundamentals of the subject and wants a convenient text with the right flavour to which he may refer for theorems and results when required in the course of his studies; secondly, that of the learner of the subject who needs to absorb the fundamentals from a systematic and logical treatment of the most up-to-date type. For the first class of user the exposition here given is wholly admirable. It does not matter to such a user how the fundamental functions are defined or how the fundamental connexion between thermodynamics and statistical mechanics is established. It will fill his requirements if important theorems are clearly set out without omissions, and the results of the statistical construction of thermodynamic functions given properly. From this point of view the treatment is admirable.

For the second class of user the treatment is, in the opinion of the reviewer, not so satisfactory, but his complaints are directed rather against the general fashion in thermodynamic exposition than against the book under review. He cannot help wishing that more attention had been devoted to giving a more logical exposition of the fundamentals on the basis of mechanical concepts without the introduction of undefined thermal concepts, somewhat after the manner shown to be possible by Born in his series of expository articles in the *Physikalische Zeitschrift* (1921), based on the ideas of Carathéodory, which Born greatly simplified. The reviewer fears he is fighting a losing battle over this. Few other students of thermodynamics appear to share his tastes and prejudices in this matter, but he is unrepentant. The logical beauty possible by the Born-Carathéodory approach is very great and extremely satisfying. The clarity gained by beginning the development of the theory of heat at the beginning with the *Zeroth* Law of Thermodynamics, the *existence of temperature* (on an empirical scale) with only the concepts of mechanics assumed *a priori*, is outstanding. But these admittedly are matters of taste.

Another matter of taste, on which the taste of the reviewer differs violently from the authors, is the introduction of absolute entropy. Now that the old abuses and errors associated with this idea have all been swept away, no great harm is done, if it is agreed that entropy can and shall be so defined that the entropy of every perfect crystal is zero at the absolute zero of temperature. There is no need to do so, but it is generally agreed that there is a gain in elegance in so doing. But the absolute entropy in common use is only absolute in a rather sophisticated way. What is of practical utility is almost always entropy statistically defined but with *nuclear spin weight omitted*, which has the limit zero in theory and practice when one extrapolates to zero ideal calorimetric measurements from any hitherto accessible temperature range. An absolute entropy which tends to zero at zero temperature for any material assembly is definable but probably not often practically realizable, and should be introduced with much circumspection. Nor need it be made the keystone of the Third Law of Thermodynamics, nor Nernst's Heat Theorem deduced therefrom. Such is the private taste of the reviewer—probably nowadays an unnecessary prejudice derived from scars on his mind caused by much study of the appalling nonsense written about absolute entropy in the days before Ehrenfest and Trkal showed how futile it is to discuss the dependence of entropy on the number of systems in an assembly without including means by which that number can be varied reversibly. Associated with the presentation of absolute entropy is the type of connexion adopted between the thermodynamic functions and their statistical counterparts. The connexion adopted here is to make the direct connexion in Boltzmann's manner between entropy and a suitably defined 'probability'. Again the reviewer must admit that he dislikes this method, and considers that the connexion should logically be made through the Second Law and showing that the statistical method provides two functions of the state of the matter in question with the right properties to play the parts of T and S in the equation $dQ = TdS$. This is again a matter of taste.

To sum up, mainly from the point of view of the instructed user, this is an extremely valuable book. The physical chemist who knows his way about it will be well equipped with the fundamentals of his trade. There is a good and comprehensive index, but in view of the scope and variety of subjects treated, one may perhaps regret that an elaborate table of contents was not provided as well. Perhaps this may be done in the next reprint. The book should be widely used.

R. H. Fowler.

WORLD FLORAS

Geographical Guide to the Floras of the World

An Annotated Selected List of Floras and Floristic Works relating to Vascular Plants, including Bibliographies and Publications dealing with Useful Plants and Vernacular Names. Part 1: Africa, Australasia, Insular Floras, North America and South America. By S. F. Blake and Alice C. Atwood. Pp. 336. (Washington: United States Dept. of Agriculture Miscellaneous Publication No. 401, 1942.) 75 cents.

A COMPREHENSIVE world list of regional floras has long been a desideratum. It is now halfway to being realized by the publication of this volume, the first of two parts which aim at providing "an annotated summary of the available, nominally complete publications on the vascular flora and the economic botany of the world", complete up to 1939. No list of the scope of this one has previously been published. While it enumerates more than 3,000 titles, its aim is usefulness and not bibliographical completeness. Papers dealing with only a section of the flora of any region, monographs and revisions of genera or families, or those works which are primarily ecological are excluded, as are all works of a 'popular' type intended for beginners.

The publications listed under each geographical area are arranged under two headings: first, general works covering the whole region, followed by local floras dealing with smaller areas within the greater. Each publication is listed in full only once, but cross-references are provided. Annotations appended to each work indicate the scope of its contents, such as the presence or absence of information as to topography, geology and climate and exact geographical area covered where this is loosely conveyed in the title, data as to previous botanical exploration, ecological information, the inclusion of vernacular names and presence or absence of a bibliography. The total number of species described or listed in each work quoted is usually given.

The catalogue affords data for a summary of the knowledge of the floras of more than half the world, and such a summary is given indicating those regions with and without floras and those insufficiently known or inadequately covered by published works. Australasia and Greenland are the best served with systematic works; and South America, with half its countries lacking even a comprehensive list of species, is the least well known. It is more surprising to learn that in the United States "a severe critique might reduce to not more than about 13 the number of States with moderately satisfactory floras".

This is an invaluable reference work and the part dealing with Europe and Asia will be eagerly awaited. The detailed geographical index facilitates ease of reference, and there is also an index of authors.

W. A. Sledge.

COLONIAL LABOUR AND SOCIAL DEVELOPMENT

MAJOR ORDE BROWNE, labour adviser to the Colonial Secretary since 1938, has presented nother of his valuable surveys, which have already covered Northern Rhodesia, the West Indies and West Africa. The latest report, which deals with ecent labour conditions and recommendations for development in Ceylon, Mauritius and Malaya*, is marked by the same emphasis on the point that labour problems can be adequately analysed and met nly in the context of general social development; nd on the consequent need for simultaneous advance n many fronts. There is also recognition that it is often desirable to make haste slowly by means of a careful search for the most practical and comprehensive policy.

The comparative prosperity and the considerable dvances in representative government have given labour problems in Ceylon very considerable political prominence, and this has been enhanced by the arge-scale immigration of Tamil labourers from India. The Government of India has effectively intervened to safeguard conditions of labour for its own nationals. Ceylon also presents in fairly typical form the problems of the three distinct forms of Colonial labour—on plantations, mines and in the towns—and many of the issues that are taken up, such as the security of migrant plantation workers, the high living costs in relation to wages of urban labourers, and the problems of health and housing, have a onsiderably wider application in the British Colonial Empire.

On the plantations, now mainly devoted to tea, he owner-planter has steadily given place to the ompany, the directors of which instruct the manager from afar with limited knowledge of changing local conditions, while the immigrant Tamil labourers, eturning less frequently to India, are becoming stabilized as a permanently transplanted population. Old standards and practices such as housing in 'lines' uitable only for temporary occupation, and direction of labour through headmen who recruited and controlled indentured labour, have become seriously outmoded and tend to bar further progress. At the same ime, agreements with the Government of India have mposed on the estates obligations with regard to medical care and schooling that are normally regarded as falling upon Government.

Major Orde Browne asks for a new departure, slow though it may be of full achievement, based on the recognition of the new situation, so that plantation labourers and their families can live in their own communities and be provided with adequate social services, as well as housing, which would no longer be dependent on their continued employment on a particular estate, and he advocates in certain areas the creation of village settlements under Government auspices to achieve this end. Meanwhile, he suggests other means to deal with what is one of the knottiest problems associated with the plantation system, namely, that of providing adequate security of tenure for the labourer without invading the rights of the management, obviously essential in the last resort, to dismiss unsatisfactory workers. Dismissal of a plantation labourer often leaves him a landless stranger in an alien community with no home or means of support for the household which he has brought with him. In the past there has often been no alternative between dismissal and allowing unsatisfactory conduct to go unpenalized. To meet this Major Orde Browne suggests an approved scale of fines subject to the consent of the labour officer and with a right of appeal.

The Indian labour on the plantations and in the towns is now estimated to approach seven hundred thousand in all. In conjunction with growing pressure on the land occupied by the indigenous Ceylonese, this situation has produced a growing communal friction based on jealousy of the Indian workers who, in their greater dependence and amenability, have advantages from the point of view of the estate or office manager and are at the same time protected by regulations secured by the Government of India. There is little doubt that Tamil labour enjoys a privileged wage position as compared both with his fellow in India and with Ceylonese in Ceylon. This discrepancy may be fanned into a very serious political cleavage, and obviously requires, even where friction is based on misconception, prompt and persistent action in a territory where the movement towards self-government is so far advanced. Among other proposals to eliminate this serious source of friction between Ceylonese and Indians, it is recommended that the existing legislation safeguarding the conditions of employment of Indians shall be extended to apply universally.

Urban conditions in Ceylon, as so often elsewhere, are found to be less satisfactory than would be commonly supposed, since paradoxically enough social ills may be less readily perceived in towns than in even remote rural areas. The root of the difficulty is the divorce of the urban labour from that considerable degree of self-subsistence in food, housing and other domestic needs which the rural population can combine with wage-labour. Above all, house (or rather in most cases room) rents which, particularly in Colombo, for a variety of reasons including shortages and insufficient use of local materials have been very high, absorb a most disproportionate amount of wages, the real value of which are in consequence far less than those of the rural labourer. A recent inquiry revealed that the incomes of the lowest paid workers in Ceylon, even when in continuous employment, were insufficient to maintain a barely adequate standard of nutrition and shelter. In this connexion the Mauritius report refers to a salutary example, in the Bell Village estate, of an impulsive and ill-conceived housing development which rapidly became derelict owing to insufficient investigations into siting, constructional and other requirements.

A similar need to avoid too rapid an establishment of Western forms, as distinct from pressing on towards Western standards, is apparent in the field of labour organizations. Trade unionism in Ceylon is embryonic and finds little sustained support among workers, in either a consciousness of solidarity or a capacity for organization. The would-be trade union organizer has too often been an outsider, sometimes disaffected, who sees a career and way to achieve some degree of personal power through the urging of his notions of the methods and objectives of unionization on inexperienced groups of workers. The social implications are clear. Union organization as a means of raising living standards and working efficiency through collective bargaining can only be satisfactorily developed *pari passu* with the advance in education and in a genuine sense of community of enlightened interests among the workers themselves. While the dangers that the vulnerability of unorganized workers may be abused are real, the activities of ephemeral and sometimes bogus labour organizations which do not command the loyalty of workers or serve their genuine interests may be ultimately as harmful to their welfare and working conditions. A significant instance of often serious indifference among the people themselves to improvements in working conditions and hours, when immediate money returns are held to be paramount, was found among Chinese brick workers in Malaya, who refused to agree to the curtailment of an 84-hour week.

---

* Labour Conditions in Ceylon, Mauritius and Malaya. Report of Major G. St. J. Orde Browne. (Cmd. 6423.) Pp. 114. (London: H.M. Stationery Office, 1943.) 21*s*. net.

The difficulties in applying Western standards of social security in Colonial territories like Ceylon and Malaya, where even under conditions of comparative prosperity national income and Government financial resources are so limited, becomes very plain. It would have been interesting in this context to have learnt how far work on plantations and in the towns has undermined the solidarity of family group life. These groups frequently provide their own mutual insurance and spreading of risks under peasant conditions. But they have proved very vulnerable in many territories to the introduction of personal incomes from wage labour. Their protection against rapid disintegration while alternative forms of group organization or social services are developed in their place poses a serious problem in applied sociology.

The vicious circle of poverty, under-nourishment, poor health and low output of labour, which does not in consequence earn an adequate purchasing power, is more than generally obvious in Mauritius. The attempt to break this circle should, as Major Orde Browne emphasizes, underlie all development plans and in particular it should include full attention to the need for improving the feeding and thereby the health of the rising generation through the provision of school meals and other means of raising nutritional standards.

As has been indicated, these reports emphasize the need for a comprehensive view of the context of Colonial labour problems. Of the many lessons to be learned there is perhaps special need for emphasis on one which does not find direct expression in the reports themselves. Major Orde Browne alludes at every turn to the lack of adequate data for the analysis of the actual situations and confident formulation of policy. He makes some recommendations for additional appointments and duties in the Labour Departments; but the complexity of the problems and the many gaps in existing information all point to the need for the earliest possible programme for social surveys in the Colonial Empire by trained investigators. Reports such as these leave little doubt as to the general nature of the problems, but for the proper selection and integration of development projects a more adequate and comprehensive body of empirical data is needed. We have so far in the British Empire paid too little attention to the development of applied sociology, to the training of field workers and the organization of comprehensive investigations. Much could be learned from substantial American experience and achievements in this field. The latter have been remarkable for their investigations and the planning of remedial projects in backward or depressed areas. Colonial development offers one among several opportunities for the fruitful application of the social sciences, and valuable work of this kind is beginning in the West Indies. The provision and harnessing of a sufficient body of workers, trained in social anthropology, survey methods and rural economics needed for this task are long overdue. Such training and organization will take time, and the earliest start should be made in preparing for them immediately after the War.

DARYLL FORDE.

MODERN DRUGS AND TROPICAL DISEASES

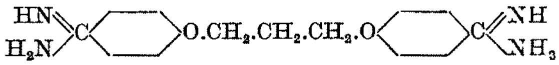
WHEN primitive man first began to use tools, he presumably employed stones or branches which he found fortuitously in shapes suitable for his purpose. Later he learnt how to fashion implements by simple modifications of pre-existing material, and in recent years he has built the vast and complicated machines which now sustain our modern civilization. A similar, but less extensive, progress can be seen in the realm of therapeutics. For long ages medical men were restricted to simple herbal and mineral remedies; then steps were taken to isolate the active alkaloids and other principles and to make simple chemical modifications in them; lastly, since the days of Ehrlich and his predecessors, therapy has come to rely more and more on compounds synthesized especially for this purpose by the organic chemist, on lines previously unknown in the vegetable, animal, or mineral worlds. This modern state of drug therapy is well illustrated by a discussion which was held at the Royal Society of Tropical Medicine and Hygiene on July 14 on "Modern Drugs in the Prevention and Treatment of Tropical Diseases". The only drug of natural origin which was mentioned was quinine, the purified alkaloid from cinchona bark. All the other substances discussed were compounds which have been prepared for the first time not more than ten or twenty years ago.

The chief speaker was Colonel S. P. James. He began by referring to the great contributions made to our knowledge of the subject by the late Prof. Warrington Yorke, whose recent untimely death was also deplored by other speakers. Yorke was the first to examine scientifically by controlled experiments the practice of trying to sterilize a malarial infection by giving quinine in very large doses for a long period. He made three outstanding observations. The first was that quinine, however and whenever it is given, does not prevent infection from the bite of mosquitoes carrying malaria. The second was that, at the onset of the primary attack, quinine has no action at all until a good many parasites are present in the peripheral blood. The third was that quinine, however and whenever it is given, does not prevent malaria from relapsing. The therapeutic value of quinine and of the other main antimalarial compound mepacrine ('Atebrin') lies in their power to prevent the infection from developing into the clinically recognizable disease (suppressive treatment or prophylaxis) and to cut short the actual attacks of the disease (curative treatment). Although it is not possible to kill off all the malaria parasites in the body, and although, when treatment has ceased, they will sooner or later reappear causing a relapse, complete cure will eventually be produced by the development of immunity in the patient after a number of attacks have occurred. To control the clinical manifestations of the disease in this way, quite small doses are sufficient, for example, 10 grains of quinine or 0·1 gm. mepacrine given three times a day. Doses larger than these produce no greater therapeutic result (apart from the 'loading' dose mentioned below) but only exert a toxic influence on the patient, who exchanges the poison of the parasite for that of the physician.

The explanation of these limitations on the action of antimalarial drugs must lie in a more complete knowledge of the biology of the malaria parasite. As is well known, there is an asexual cycle in the blood of man in which the parasite (trophozoite) gradually enlarges and then divides (schizogony) into 16 or 32 small forms, each of which enters a new blood corpuscle and becomes a new trophozoite; in benign tertian and malignant subtertian malaria this cycle occupies forty-eight hours. There is also the invertebrate cycle, starting from the sexual cells (gametocytes) swallowed by the mosquito, which conjugate and form cysts in the insect's stomach; these cysts liberate countless smaller forms (sporozoites) which pass into the salivary glands and are inserted into man again when the mosquito bites; this cycle occupies about ten days. These two cycles have been known for forty years, but there is considerable obscurity as to the stages which occur between the injection of the sporozoites into the new host and the appearance of parasites (trophozoites) in the blood; in human infections this latent period occupies about two weeks. The work of James, Raffaele and others has shown that in certain types of bird malaria (due to *Plasmodium gallinaceum* and *P. relictum*) the sporozoites first develop in endothelial cells and macrophages, and not in the red blood corpuscles (erythrocytes) which form the host cells for the well-known asexual cycle of trophozoites and schizonts mentioned above. These new forms are known as the 'exoerythrocytic' parasites. Presumably they ultimately give rise to the ordinary trophozoites. They are almost completely resistant to the action of the antimalarial drugs known at present; in young birds they often reappear after the main wave of the blood infection has been overcome, and they cause death from massive growth in the capillaries of the brain and other organs. The occurrence of such exoerythrocytic forms in human malaria would explain many of the limitations of drug therapy described above, but unfortunately such forms have not yet been demonstrated. Col. James expressed his belief that they would eventually be found in man, but other speakers were more sceptical.

Be that as it may, the importance of intensive research on the biology, chemotherapy, and other aspects of the malaria parasite ought to be clear to all. In the War of 1914–18, malaria was an important military factor, and apparently it looms large in this War also. According to a recent broadcast by a member of the Australian Government, 80 per cent of the Australian troops who were landed in New Guinea went down with malaria. Although the details about other localities are rightly withheld by the authorities, it requires little imagination to visualize the great handicap to military operations and the great losses in men's efficiency and lives which this disease must be causing. Money devoted to the search for weapons to combat such a deadly menace is money well spent. Unfortunately, this truism has not been properly appreciated in Great Britain during the last thirty years, and support for such research has been limited, etiolated, and spasmodic. The sums spent on the conquest of malaria have been insignificant compared with those employed in trying to persuade people to change their brand of cigarette, or to alter their opinion about the nutritive value of beer. This is the more surprising since so many British Colonies lie in the tropics; and non-British have been apt cynically to express surprise that the wealthy British Empire, which probably suffers greater harm from malaria than any other community in the world, has been content to depend on the Dutch of Java for its quinine and on the German chemists for its synthetic antimalarial compounds. Colonel James concluded by hoping that this sorry state of affairs would be remedied in the future.

The next speaker, Dr. F. Hawking, described the valuable contributions made by Prof. Warrington Yorke to the chemotherapy of trypanosomiasis (sleeping sickness). By devising a simple technique for maintaining trypanosomes alive *in vitro*, he made it possible to study the action of drugs on the parasite without the complications and obscurities due to the intervention of the animal host. By this means Yorke showed that arsenicals exert a direct action upon the trypanosomes. Further work showed that normal trypanosomes actively absorb the drug, which becomes concentrated in the parasite and eventually poisons it. On the other hand, trypanosomes which have become arsenic-resistant or 'arsenic fast' fail to absorb the drug and so they survive. This explanation of the resistance of arsenic-fast trypanosomes, which had been postulated by Ehrlich on theoretical grounds, thus received its experimental verification. Yorke's last big contribution to chemotherapy was the discovery (in collaboration with Dr. H. King, Dr. A. J. Ewins and others) of the diamidine compounds such as propamidine:



These compounds are very active in the treatment of human trypanosomiasis, but the dose is limited by their toxicity; moreover, they do not penetrate the central nervous system, so that infections which have reached the brain cannot be sterilized. Accordingly it is probable that they will not replace the compounds at present in use, namely, tryparsamide and suramin (Bayer 205). On the other hand, they have proved very valuable in the treatment of kala azar, especially in the case of the resistant type which occurs in the Sudan, and this will probably prove their most important field of use. They are also effective in the treatment of babesiasis of dogs and other animals. Recently through the work of Fuller, and of Thrower and Valentine, propamidine has been found to exert a powerful action against bacteria and it has been employed with much success as a dressing for burns and other superficial wounds.

The greatest triumph of modern chemotherapy has been the discovery of the sulphonamide compounds, following the description of prontosil, by Domagk in 1935. Many of the bacterial infections of temperate climates which respond to these compounds occur in the tropics also; and sulphonamides have been invaluable in the Colonies in the treatment of pneumonia, cerebrospinal meningitis, gonorrhœa and other conditions. Among the infections more specifically tropical which are cured by these drugs, the chief one is bacillary dysentery. Dysentery is one of the four or five major infections of the tropics, and the introduction of sulphaguanidine by Marshall in 1940 has revolutionized its whole treatment. Previously the physician could apply only palliative measures, and the recovery of the patient depended mainly on the power of his constitution to overcome the invading micro-organisms. Now, the infection can be cut short in its early stages by a direct attack upon the offending bacilli. Dysentery has affected many of our troops in the Middle East, although the incidence has been kept much lower than it was in the War of 1914–18 by strict measures concerning the disposal of fæces and fly control. The use of sulphaguanidine has cut short the period spent in hospital, avoided much chronic invalidism and saved many lives. Yet another major disease has been brought under the control of the sanitary inspector to prevent it, and of the physician to cure it.

Another disease, more dreaded but less common, which responds to sulphonamide therapy is plague. In 1941 there was an epidemic in Nairobi, involving more than 240 patients, and Plum found that sulphapyridine given in large doses to early cases produced a dramatic improvement in their condition; if the treatment was not given until later, the infection was often too far advanced for the patient to be saved. Unfortunately other important infections of the tropics such as undulant fever (due to *Brucella melitensis*), typhus and typhoid are not affected by sulphathiazole and similar compounds.

Sulphonamides have a moderate action against human malaria, an action which is greater on malignant subtertian than on benign tertian. But since this action is less intense than that of the drugs at present in use (quinine and atebrin), its existence is of little practical importance at the present time, although it forms the starting-point for chemotherapeutic research which may eventually yield more active remedies.

The older forms of chemotherapy, such as those for malaria and for sleeping sickness, have something to learn from the newer principles which have been evolved from experience with sulphonamides. For one thing, the rational use of synthetic drugs is greatly facilitated if their blood concentration can be estimated and the dosages regulated accordingly. In the case of suramin (Bayer 205, antrypol) used for sleeping sickness, this is already possible through the work of Prof. A. C. Wormall; and the treatment of Europeans affected with the disease ought to be controlled in this manner, in order to avoid the disastrous relapses which may occur in patients who fail to retain the compound in adequate amounts. In the case of mepacrine (atebrin) used for malaria, methods will shortly become available, and then revision of the doses accepted at present may be necessary. A second principle derived from experience with sulphonamides is the rule of starting treatment with a large initial 'loading dose'. In this way, the unnecessary delay in raising the blood concentration to its effective level by a gradual accumulation of equal small doses can be avoided. Such a practice might well be adopted when mepacrine is administered for an acute attack of malaria. Instead of giving the customary course of 0·1 gm. three times a day for five days, in which case an effective concentration in the blood is probably not reached until the second day, it was suggested that the first dose might well be 0·6 gm. (or even 0·9 gm.) and that subsequent doses should be correspondingly reduced. It was also pointed out that although intramuscular injections of mepacrine are sometimes necessary, and although they are effective in getting the drug into the blood rapidly, they always cause a certain amount of necrosis at the site of injection, and should be avoided whenever possible.

Other speakers in the discussion described their own experiences with drugs and tropical diseases. Dr. H. M. Hanschell said that propamidine exerted a powerful curative action on infections of *Trichomonas vaginale* or of Ducrey's bacillus, but it was not more effective than the remedies already in use, and it often caused toxic symptoms; consequently it was not likely to be adopted for routine use in these diseases. He defended the synthetic chemists against some of the slurs cast upon them, saying that if they were expected to produce new drugs against infections, they ought to be given more information about the biology of the micro-organisms; this information could be gained only by more extensive research upon the malaria parasite and other offending Protozoa and bacteria.

Prof. K. B. Williamson mentioned some personal experiences with malaria in Malaya.

Major J. W. Howie, who had recently returned from Nigeria, described observations on soldiers taking quinine. Some persons failed to absorb the quinine completely in the intestine, or they got rid of it from the body with abnormal rapidity, and these persons were not properly protected by prophylactic quinine against the onset of attacks of malaria, nor were they readily cured by it when quinine was given for their fever.

Dr. W. D. Nicol brought forward observations made by himself and Mr. P. G. Shute at the Ministry of Health's Malaria Laboratory at Horton. Suitable doses of mepacrine given to four volunteers had prevented all infections from the bites of mosquitoes infected with subtertian malaria. In these cases, mepacrine had acted as a true prophylactic, destroying the sporozoites which the insect injected.

Dr. A. R. D. Adams spoke as one who had long been associated with Prof. Warrington Yorke, to whom he paid high tribute. The diamidine compounds had been used for the successful treatment of several cases of Indian kala azar at the Liverpool School of Tropical Medicine and no toxic complications had been encountered.

Major-General A. G. Biggam was able to give more cheering information about the other diseases of our forces in the tropics. The use of sulphaguanidine for the treatment of bacillary dysentery has been most satisfactory, and in most patients the progress of this disease is rapidly cut short. Succinyl-sulphathiazole (sulphasuxidine) is equally effective and satisfactory, although presumably the supply is more limited. Sulphapyridine and sulphathiazole are effective therapeutically, but they are more likely to cause toxic effects (vomiting and blockage of the urinary passages). Sulphanilamide is not effective. Succinyl-sulphathiazole has also been tried against typhoid fever; against the infection itself it is powerless, but it may help to prevent distension, although this is not certain. Kala azar in the Sudan responds well to stilbamidine (introduced by the late Prof. Warrington Yorke), but unless the solution is freshly prepared toxic reactions may occur. Tropical ulcers which often occur on the legs, and which are a most important cause of disability among native workers, have been much improved by the local application of penicillin, although presumably the supply is too limited for this treatment to be used extensively. Relapsing fever due to *Trep. recurrens* has caused trouble in Abyssinia and the Middle East; in some places, the response to neo-arsphenamine has been disappointing, and stovarsol, tryparsamide or bismuth have been more satisfactory. When the medical history of the present War can be described in full, because peace has come, it will include many interesting features. F. HAWKING.

ANTOINE LAURENT LAVOISIER, 1743–1794

By PROF. J. R. PARTINGTON, M.B.E.
Queen Mary College, University of London

ANTOINE Laurent Lavoisier, the architect of modern chemistry, was born in Paris on August 26, 1743. His father was an advocate and his mother the daughter of an advocate. The fortunes of the family of Lavoisier had progressed from employees in the postal service, through trade, to the legal profession, and although the father was not wealthy, the maternal grandmother had ample means and arranged for the boy's education. He attended as a day scholar at the famous Mazarin College in Paris, then notable in providing excellent teaching in science. Here he remained to the age of seventeen, when he began to prepare to enter the profession of law. His teachers, Guettard in geology, Bernard de Jussieu in botany, and especially Rouelle in chemistry, had, however, implanted in him a love of science. At first he was most attracted to mathematics and meteorology. He acted for three years as assistant to Guettard in a survey for a geological map of France. In the intervals of the necessary journeys he wrote an essay for the Royal Academy of Sciences, which had offered a prize for a description of the best method of lighting the streets of a large town. Lavoisier's essay did not gain him the prize, but he received a gold medal and the honour of having his essay published.

This early association with applied science was to continue throughout his life, and he later carried out a very large amount of work in the service of the French Government. The latter, during the early part of the seventeenth century, and in association with the Royal Academy of Sciences, had taken a keen interest in the application of science to arts and industries, and the spirit of the organization of knowledge which found its expression in the "Encyclopædia" was also manifested in the publication of several large and richly illustrated volumes dealing with various trades. The idea that it is a matter of political importance to have existing knowledge summarized and rationalized for the public benefit is, therefore, not a new one, and it found extensive and fruitful application in pre-revolutionary France. The six large volumes of the collected works of Lavoisier, published in the period 1864–93, are largely devoted to his many investigations on applied science, such as the manufacture of gunpowder, and he gave a large amount of time and energy to such public services.

The Royal Academy of Sciences, founded by Louis XIV in 1666, elected Lavoisier to membership in 1768, at the early age of twenty-three. In 1764 he had published a paper on gypsum, but at this time he had done no scientific work of real importance. In 1768 he also entered the *Ferme Générale*, an association which, in return for a sum paid to the Government, fixed periodically, had the right to collect from the taxpayers whatever sum they could be induced to part with. As might be expected, the members of the *Ferme* varied considerably in their methods, and there was some harsh administration, so that the association as a whole laid up for itself a growing store of hatred and contempt which was later to play a large part in the Revolution. Whatever pretext was offered for the execution of Lavoisier, it was actually his association with the *Ferme* which sealed his fate. He carried out his duties honestly and, we may be sure, humanely, but he also made large profits. These enabled him to carry on very expensive researches, and his work is noteworthy in the use of elaborate—often over-elaborate—apparatus, and much of it was outside the means of other scientific men.

In 1771 Lavoisier married Marie Anne Pierrette Paulze, the daughter of a member of the *Ferme*, then in her fourteenth year. Madame Lavoisier, although so young, set herself the task of becoming an assistant and amanuensis in his scientific work, and besides being a capable and affectionate wife she also, with her notable linguistic and artistic ability, gave him very effective help in his researches and publications. The charming illustrations in his famous "Traité élémentaire de Chimie" (1789) are from drawings which she made.

The scientific work of Lavoisier has a marked character. He discovered no new substances, devised no really novel apparatus, and worked out no improved methods of preparation. He was essentially a theorist, but a theorist of a most original, drastic and revolutionary kind. It must not be supposed that scientific chemistry originated with him, although he undoubtedly gave it a new form, which it still carries. From the beginning of the seventeenth century, with the work of such men as Van Helmont, Boyle, Glauber, Lemery and Stahl, a very important body of systematized knowledge had grown up which constituted a true science of chemistry. The underlying theory, when Lavoisier began his work, was the doctrine of phlogiston. This was primarily intended to explain the phenomena of combustion and the calcination of metals. The theory assumed that combustibles and metals contained a common, identical, and transferable entity called phlogiston, which they lost when burnt or calcined; the theory was also widely extended to other chemical phenomena. There had also been good quantitative work, notably that of Black (whose researches served as a model for Lavoisier's) and Bergman. The focusing of attention on combustion phenomena by Lavoisier, and the overwhelming importance which he conferred on oxygen, must not be allowed to obscure the fact that a large part of chemistry lies outside this region, and that much fundamental and important research had already been carried out in this wider field.

Lavoisier's great merit lay in his capacity of taking over experimental work carried out by others (whose claims he, unfortunately, did not always sufficiently recognize or admit in his published memoirs or his books), and by a rigorous logical procedure, based on the results of quantitative experiments which he himself made, of expounding the true explanation of the results. This explanation, that combustion and calcination consist in the union of the combustible or metal with oxygen, found much opposition among the older and more conservative chemists in all countries, but after the publication of his "Traité" in 1789, it quickly gained acceptance everywhere, no less rapidly in Germany, the home of the phlogiston theory, than elsewhere. This was, however, only a part of the story. The appearance of heat and light, or fire, in combustion also required explanation, and Lavoisier did this by assuming the existence of imponderable elements, caloric (the matter of heat) and light, which in their way bore a strong resemblance to the old phlogiston.

This work began in 1772, and after the discovery of oxygen by Priestley in 1774 it proceeded apace, a large number of memoirs being published by Lavoisier after presentation to the Royal Academy of Sciences. The experiments of Cavendish on the formation of water from hydrogen and oxygen, published in 1784, enabled Lavoisier to complete his so-called Anti-phlogistic Theory, and they played a decisive part in leading to its acceptance. The assumption made by Lavoisier that all acids contain oxygen was an error which was not rooted out until after 1810, but his surmise that the earths are oxides of unknown metals received a brilliant confirmation in Davy's isolation of the alkali and alkaline earth metals in 1807–8. The alkalis themselves were not regarded by Lavoisier as oxides of metals, although he was convinced that they were not true elements.

A great service given to chemistry by Lavoisier was the institution, with his colleagues, at the instigation of Guyton de Morveau, of a scientific nomenclature, published in 1787. The principles laid down are still in use.

The same year, 1789, which saw the publication of Lavoisier's revolutionary "Traité de Chimie" witnessed also the outbreak of the French Revolution. During its earlier stages Lavoisier continued to carry out work for the State, but he was soon singled out for attack. The impulse came from Marat, whose theory of fire had been unfavourably criticized by Lavoisier. The series of pretexts by which he was brought into popular discredit cannot be detailed; in the final phase nothing worse could be brought against him than a charge that he had, as a *fermier*, adulterated tobacco with water. In his trial, in which the president of the court was Coffinhal, the plea that his scientific services had been valuable to the State was rejected in the words: "The Republic has no need of savants; justice must take its course". Although Lavoisier's association with the *Ferme* was the real reason for his downfall, this could not legally be brought against him, since the Tribunal had no power to deal with crimes of the pre-Revolutionary period. With a will, however, a way can be found, and on the petty accusation mentioned the great Frenchman was condemned, and on May 8, 1794, he suffered the penalty of death by the guillotine.

In 1795 his property, previously confiscated, was restored to Madame Lavoisier, who lived until 1836; in 1806 she published some memoirs of her husband. His complete works were, as mentioned, published under the auspices of the Royal Academy of Sciences in the period 1864–93. The general contributions of Lavoisier to chemistry are well known, and he has received an ample and generous recognition and admiration, which are well deserved. It is fitting, however, on the date of the bicentenary of the birth of this distinguished man, once more to pay a tribute to his great and enduring services to science in general, and particularly to chemistry.

ARCHÆOLOGY AND ANTHROPOLOGY IN INDIA

By Prof. J. H. HUTTON, C.I.E.
University of Cambridge

It is just about a hundred years since an association began to be formed between archæology and anthropology which has proved very fruitful to both these branches of human knowledge. So necessary are they one to another that no general course of instruction in one can well afford to ignore the other, and the union of the two in a common tripos in the University of Cambridge, due no doubt in the first instance to the foresight and influence of Haddon and Ridgeway, has proved incontestably satisfactory. But this association between archæology and anthropology has been generally limited to prehistoric archæology on one hand, and on the other to the more or less historic schools of anthropological thought; for the more extreme, at any rate, of the so-called functionalist anthropologists profess to repudiate inquiry into the past history of the societies and institutions which they study. In his presidential address to the Section of Anthropology and Archæology at the thirtieth Indian Science Congress held in Calcutta in January of this year, Dr. N. P. Chakravarti, of the Archæological Survey of India, seeks to extend this association by turning epigraphy to the service of anthropological inquiry.

The period of Indian history from the third century B.C. to the sixth century A.D. is indeed obscure enough. It was a period of minor immigrations between that of the Rigvedic 'Aryans' in the second millennium B.C., and the influxes of Islamic conquistadors which started about the ninth century A.D. with the Arab incursions into Sind, and continued until the establishment of the Mogul Empire. It was the period of the Yavanas, Pahlavas, Sakas, Kushāns and Huns, and inscriptions can at least throw some light on the areas that these invaders occupied, and, in the case of the Kushāns, at any rate, whence they came. Further, the way in which they adopted the religion of the country they settled in is clearly indicated by their votive inscriptions. Thus a pillar in Gwalior State records the dedication of a shrine to Krishna by Heliodorus son of Dion, ambassador of Antialcidas, the Hellenic king of Taxila, and describes the dedicator as a 'follower of Vishnu'. In a similar way one of the Kushān rulers is shown by his coins to have been a Shaiva.

Inscriptions of the same period likewise throw light on peoples long settled in India, such as the Andhras, whose rulers can be shown to have intermarried with Saka invaders, and Dr. Chakravarti mentions inscriptions of the Ishvaku family of southern India which show clearly that, although it is prohibited by the strict Hindu law, cross-cousin marriage was practised even in ruling families. Other inscriptions perhaps go to indicate an identity of race between ruling families at this period in Assam and in Gilgit, a point which calls up the reflexion that the game of polo was first known to us in Gilgit and in the distant State of Manipur on the eastern frontier of Assam, whence it was introduced into British athletics, though it is the Balti and not the Manipuri name for it which we use. The sum total of information available to ethnographers from inscriptions may not be great, but such as it is, it is likely to be useful and suggestive.

Dr. Chakravarti also dwells on the subject of writing in general. He describes four stages, the first three of which he calls mnemonic, pictorial, and ideographic, while by the fourth the alphabetic is clearly intended. But he is not justified in describing them as successive evolutionary stages. The first two may no doubt be regarded as both contributing to the invention of writing, but there is no evolutionary series here. The alphabet, again, for all true alphabets seem to have a single source, though it has a pictographic origin, does not by any means evolve from an ideographic form of writing. On the contrary, though the Japanese in adopting the Chinese script may tend to give some of its ideograms a purely alphabetic value, Chinese, which is ideographic, has no alphabet. The nature of the Mohenjodaro script is still undetermined, and it is probably impossible to say whether it is pictographic or ideographic. It seems limited to seals, and may have been a purely commercial device for marking goods. Dr. Chakravarti mentions that many theories of its interpretation have been put forward without carrying conviction, but he does not mention specifically Hevesy's association of it with the Easter Island script. Hevesy's view has been severely criticized by Dr. Métraux of the Bernice P. Bishop Museum; but Heine-Geldern has found equally remarkable parallels between both the Mohenjodaro and the Easter Island symbols and those used in one of the earliest forms of Chinese. If he and Hevesy are right—a view not very easy to accept—it is possible that the language of Mohenjodaro may prove to have belonged not to the Dravidian but to the Austric family, and so to have affinities with the Munda tongues.

Dr. Chakravarti's address has been taken in reverse order. It remains to mention a subject that he touched upon at the start: that is, the losses suffered by anthropology in India during the past year through death. Of the names he mentions, only two are Indians, one an anthropologist, the other an archæologist. Rai Bahadur Sarat Chandra Roy was well known to anthropologists outside India as a pioneer in Indian ethnography. His monographs on various tribes of Chota Nagpur were among the first of their kind and have contributed very greatly to our knowledge, and understanding, of those tribes, to the promotion of whose welfare he gave so much of his life. It was the oppressions and hardships suffered by the Munda tribe at the hands of aliens that first moved him, as a young lawyer, to study their language and customs the better to sponsor their causes. Furthermore, he founded and edited *Man in India*, which is still the only periodical in the British Empire, probably, given exclusively to anthropology, but without the backing of any scientific or educational body behind it. Roy was also something of an archæologist, and excavated a number of prehistoric sites in Chota Nagpur, particularly sites associated with the Asurs. Rai Bahadur Ramaprasad Chanda was probably more of an anthropologist than Roy was of an archæologist, for he started as an anthropologist before he gave himself to archæology, working on anthropometry and on physical data as well as on cultural. He was an early critic of Risley's theories of brachycephaly in India, but probably his most important contribution to anthropology came from his profound knowledge of early Sanskrit literature, which he applied to the interpretation of cultural problems of prehistoric India. Indian anthropology is indeed unfortunate in losing both Sarat Chandra Roy and Ramaprasad Chanda in the same year.

OBITUARIES

Baron Gerard de Geer, For.Mem.R.S.

BARON GERARD JACOB DE GEER, whose death occurred on July 24, was born in Stockholm on October 2, 1858. Professor of geology at the University of Stockholm from 1897 until 1924, he ended his days as founder-director of the University's Geochronological Institute. There is more than one Baron de Geer in Europe. The originator of the branch of the family from which the famous geologist arose went to Sweden from what is now Belgium at the request of King Gustavus Adolphus early in the seventeenth century, and there started a large iron and steel industry. In after years successive de Geers played a great part, not only in the industry of Sweden, but also in her science and politics. Gerard's father, Louis, was Prime Minister for twelve years, and Gerard himself was a member of Parliament from 1900 until 1905. Recognition in Great Britain of his scientific eminence has been shown by award of the Wollaston Medal of the Geological Society in 1920, and by election to the foreign membership of the Royal Society in 1930.

De Geer's great achievement, according to very general acceptance, has been his deciphering of a year-chronology "backwards into a part of the earlier or Palæolithic Stone Age". We have here something much more precise than any chronology so far based upon the erosion-rate of Niagara, or the decay-rate of uranium. The time unit employed is the year, just the same as that which figures so prominently in our school history books.

Recognition of annual rings of growth in trees of temperate regions is an old, old discovery; but realization of similar annual layers of growth in certain favourably situated outer portions of the earth's mineral fabric was little more than a dream, until, in 1878, it came independently into the mind of de Geer. This happened during his first geological field work in the Stockholm region. From then onwards to the end of his life, during the greater part of which time he was helped by assiduous collaborators, de Geer strove to confirm the annual nature of the layering of the varved clays of the Baltic; and thereafter to derive from the chronometer thus afforded a maximum of information regarding dates of events which had happened during Late Glacial and Post-Glacial times in Sweden and elsewhere.

The term 'varve' means a cycle. The varved clays, in large measure of somewhat sandy character, are laminated deposits, in which each full layer has a more sandy basal portion merging upwards into a skin of pure clay—which latter is followed abruptly by the sandy base of the next succeeding varve. The Baltic varved deposits were formed in a freshwater portion of the Baltic Sea, deeper and more extensive than to-day owing to submergence, into which the Scandinavian ice-sheet still projected during a retreat determined by frontal and other melting. Almost any observer would be prepared to admit that individual varves record rhythmic repetitions of some melt plus non-melt episode, which affected the neighbouring ice-sheet. He would also recognize an inherent probability that in each episode the melt portion covered a whole summer and the non-melt a whole winter, because, where flood waters are provided by melting of large expanses of snow and ice, rather than by rainfall, they tend to adopt a seasonal duration. To turn this probability into something near certainty was de Geer's fundamental task. As president of the memorable International Geological Congress that met at Stockholm in 1910, he presented his case in an address and also less formally during a wonderful afternoon excursion. His argument was as follows.

There are in the Stockholm district two other sets of glacial phenomena which independently seem to record successive seasons. The first is a series of rock-fragment ridges, obviously frontal moraines. One naturally interprets them as marking winter re-advance positions of the ice front, which, owing to preponderant summer melting, was on the whole retreating. The second is a series of great mounds of sand and gravel, strung like giant beads in a chain running at right angles to the moraines. Here the inference seems justified that each mound represents the gradually retreating mouth-position of a persistently renewed summer sub-glacial river, discharging into the standing water of the Baltic. De Geer assured us that moraines, gravel mounds and varves are all convincingly related. Thus usually only one gravel mound is situated between each successive pair of moraines, as one would expect, since there is only one summer between any two successive winters. Also, in proceeding northwards across the moraines (keeping away from complications near the gravel mounds, which make observation difficult), one finds that the bottom varve of the local varve succession is always lost each time one crosses a morainic ridge.

This last claim obviously involves identification of individual varves. De Geer found on graphing his records of thickness for successions of varves exposed in neighbouring brick pits that he obtained curves of considerable character, with diagnostic groupings of maxima and minima. These curves he interpreted as in large measure a record of climatic vicissitudes. It was clear, at any rate, that they allowed of identification of certain well-characterized varves from pit to pit. Supposing that south of a particular moraine de Geer had established that the fifth varve from the bottom was of abnormal thickness, he always found that immediately north of the same moraine it was the fourth varve from the bottom that showed this abnormal character.

The above is only an outline of the beginning of de Geer's work. One remembers how he connected graph with graph, until he had compiled a year-and-climate record reaching from the time when glaciers melted from the site of Stockholm right on to the present day. One remembers, too, his selection of a year 0, when, according to his chronology, the Glacial Period terminated and Recent Times began. This year 0 is marked locally by a monster varve, attributed to the catastrophic drainage of the glacially impounded portion of Lake Storsjön on severance by melting of its retaining glaciers. At Storedan in West Ragunda the resultant varve measures 980 mm. of clayey sediment. Again, one remembers time correlations with Iceland and the Great Lakes region of North America. One also remembers how de Geer's technique of graphing successive varve thicknesses has been applied with striking success to extracting history from the annual rings of trees, whether pines in Scandinavia or Sequoias in California. Finally, there is his observation that glacial varves are only found where summer floods have entered standing fresh water. Various explanations of this limitation of glacial varves to fresh water have been advanced.

In brief, de Geer created and maintained throughout his life-time a new sub-science. Fortunately, his main results are summarized in "Geochronologica Suecica: Principles", published in two fine volumes in English (Stockholm, 1940). This great work is dedicated to his wife, Ebba Hult de Geer, "since more than thirty years my indefatigable scientific partner during all expeditions, every kind of field-work and redaction unto the last proof-leaf". Those of us who are interested in geochronology know how much original research has entered into this invaluable and indefatigable partnership.

E. B. Bailey.

Mr. Hugh Whistler

By the death of Mr. Hugh Whistler at the early age of fifty-three, ornithology—and especially Indian ornithology—has lost a man of science who had already made his mark but who would undoubtedly have added greatly to his reputation had he been spared.

Hugh Whistler was born on September 28, 1889, and died on July 7, 1943. He was educated at Aldenham and when twenty years old entered the Indian Imperial Police. Choosing the Punjab as his Province, in a very short time his keen observation of Nature enabled him to add much to our knowledge of the distribution of birds in that and the adjoining Provinces.

In 1925 he married the Hon. Joan Ashton, daughter of Lord Ashton of Hyde, and had one son and one daughter. In 1926 he retired from the Indian Police to Battle, Sussex, where his ancestors had lived for many generations. Here he took a keen interest in local matters. He was on the Committee of the Sussex Archæological Society.

His outstanding work is, undoubtedly, his "Handbook to Indian Birds", which, published first in 1928, has already passed through three editions, each an improvement on the last. Of more scientific importance, however, were his papers on the "Scientific Survey of the Eastern Ghats" (in collaboration with N. B. Kinnear); his "Hyderabad State Ornithological Survey" (in collaboration with Salim Ali); and his "Ornithological Survey of the Jodhpur State".

His first article was published in the *Bombay Natural History Journal* (22; 1911), a note on "the distribution of *Passer pyrrhonotus*", and from that time up to the date of his death he contributed sixty to seventy articles to that journal. In addition, after his retirement in 1926, he wrote frequent notes and articles for the *Ibis* which, though brief, were of considerable value.

In his notes to the Bombay journal and the *Ibis* he recorded additions to the Indian avifauna of *Motacilla alba leucocephala*, *Emberiza calandra*, *Luscinia suecica discessa*, *Panurus biarmicus* (*russicus*) and *Pitta megarhyncha schlegel*, while he also described as new *Zosterops palpebrosa salimalii*, *Pomatorhinus horsfieldi maderaspatensis* and *Passer domesticus parkini*. In recognition of his work the following birds, among others, were named after him: *Garrulax albigularis whistleri*, Stuart Baker; *Tarsiger chrysaeus whistleri*, Ticehurst; *Niltava sundara whistleri*, Ticehurst; *Horeites brunnifons whistleri*, Ticehurst; *Seicercus burkii whistleri*, Ticehurst; *Parus rufonuchalis whistleri*, Stresemann and *Sitta Himalayensis whistleri*, Delacour.

Whistler's work was characterized more than anything else by his "capacity for taking pains"; by his extraordinary care over the most minute details, and by his methodical procedure in everything he undertook.

E. C. S. B.

WE regret to announce the following deaths:

Mr. W. H. Hogg, since 1933 principal of Seale-Hayne Agricultural College, on July 29.

Sir Ralph Jackson, formerly chief veterinary officer in the Ministry of Agriculture, on August 2, aged seventy-one.

Prof. T. J. Jehu, emeritus regius professor of geology in the University of Edinburgh, on July 18.

Dr. C. J. S. Thompson, M.B.E., honorary curator of the Historical Collection of the Museum of the Royal College of Surgeons, aged eighty.

NEWS and VIEWS

Retirement of Prof. Raymond C. Archibald

FEW scholars have a larger circle of personal friends among mathematicians on both sides of the Atlantic than Prof. Raymond C. Archibald, whose impending retirement is announced from Brown University. An official position in the American Mathematical Society has brought him into touch with every active mathematician of this century in America, while in the course of frequent and extensive journeys in Europe to ransack bookshops and visit libraries, he has taken every opportunity to make the acquaintance in their own countries of the men and women whose writings he already knew. Enthusiastic, persuasive and learned, he has made the mathematical section of the library at Brown University one of the finest to be found anywhere, and he has created there for mathematicians the surest source of bibliographical and biographical information in the world.

Prof. Archibald's published works include the definitive edition of one of Euclid's minor treatises, and the semi-centennial history of the American Mathematical Society, the latter a heavily documented volume incorporating twenty-seven biographical sketches. He is the author of a vast number of bibliographical articles, distinguished for an impersonal and uncritical thoroughness that conceals the toil and the knowledge that go to their compilation, and is, it must be confessed, sometimes carried to excess, for Archibald's modesty will not allow him to believe that if only, like Keynes and Muir, he would sometimes tell us after reading a paper that no one need ever read it again, others would gladly accept his judgment and be spared the tedium of making the discovery for themselves. Prof. Archibald has served for long periods on a number of editorial boards, and is now editing for the National Research Council of the United States the youngest of mathematical journals, *Mathematical Tables and Aids to Computation.* To Prof. Archibald, retirement will not spell indolence. It need scarcely be said that his expert advice will still be available in the library which he has made famous, he is continuing in his latest editorship, and he hopes to devote the time saved from routine to perfecting the organization of a library of English and American poetry and drama which he has been developing at Sackville since 1905 in memory of his mother. Increased leisure, if miraculously he achieves it, will mean enhanced opportunities to cultivate a second passion, for he is not merely a lover of music but also a musician of exceptional skill, who might easily have become a professional violinist and remained an amateur in mathematics. May he long enjoy a strenuous life.

Higher Education in the British Colonies

THE Colonial Office announces that the following Commission is to inquire into higher education in the Colonies: Sir Cyril Asquith (chairman); Sir Donald Cameron, formerly Governor of Nigeria; Prof. A. M. Carr-Saunders, director of the London School of Economics; Prof. H. J. Channon, professor of biochemistry, University of Liverpool; Sir Fred Clarke, director of the Institute of Education, University of London; Mr. J. F. Duff, vice-chancellor of the University of Durham; Lord Hailey, chairman of the Colonial Research Committee; Prof. A. V. Hill, M.P., secretary of the Royal Society; Sir James Irvine, vice-chancellor of the University of St. Andrews; Sir Richard Livingstone, president of Corpus Christi College, Oxford; Dr. R. Marrs, formerly principal of University College, Colombo; Miss L. H. Penson, professor of modern history, University of London; Miss Margery Perham, director of Colonial research, Nuffield College, Oxford; Prof. J. A. Ryle, professor of social medicine, University of Oxford; Dr. R. V. Southwell, rector of the Imperial College of Science and Technology; Dr. J. A. Venn, vice-chancellor of the University of Cambridge. The terms of reference of the Commission are: "To consider the principles which should guide the promotion of higher education, learning, and research and the development of universities in the Colonies; and to explore means whereby universities and other appropriate bodies in the United Kingdom may be able to co-operate with institutions of higher education in the Colonies in order to give effect to these principles".

A further commission of inquiry into higher education in British West Africa has been announced. It consists of Colonel Walter Elliot, M.P. (chairman); Prof. H. J. Channon, University of Liverpool; Mr. A. Creech Jones, M.P.; Mr. J. F. Duff; Sir Geoffrey Evans, of the Royal Botanic Gardens, Kew; Dr. Julian Huxley; Mr. K. A. Korsah, unofficial member of Executive Council, Gold Coast; the Rev. Ransome Kuti, headmaster, Abeokuta Grammar School, Nigeria; Miss E. C. Martin, vice-principal of Westfield College, University of London; Prof. B. Mount-Jones, vice-chancellor of the University of Leeds; Miss Margaret Read, acting principal of the Colonial Department, Institute of Education, University of London; Dr. E. H. Taylor-Cummings, medical officer of health, Sierra Leone; and Prof. A. E. Trueman, professor of geology, University of Glasgow. It is also to include a member with wide administrative experience in tropical Africa. This Commission is to report on the organization and facilities of the existing centres of higher education in British West Africa and to make recommendations regarding future university development in that area.

African Meteorological Workers

TRAINING of Africans in the Meteorological Department in Kenya was started some years ago and increasing numbers are now joining the Service. Most of the workers have been educated at African schools and have passed the Junior Secondary School Examination. An entrance examination to the Department ensures that the candidates have a reasonably sound knowledge of arithmetic, English, physics and geography. Sections of the Service include observing, clerical climatological work and printing. Africans trained for the Observing Section are liable to be sent anywhere in Kenya and a few have gone as far as Uganda and Tanganyika Territory. A course beforehand of a few months duration enables these men to read instruments such as thermometers and barometers. They learn to distinguish between the different types of clouds and to report weather visibility and wind force and direction. Training is also given in pilot balloon observations, and Africans have shown remarkable adaptability in this difficult task. The Climatological Section covers a wide field and here also Africans are not lacking in ability. Printing is a task to which the African takes readily, and all reports, summaries and rainfall bulletins are printed on the premises, as well as all the necessary forms for the Department. Rates of pay and facilities for leave are the same as for other Government Departments. Hours are also similar, except for the observers, whose duties must necessarily be irregular.

Integration of Research in the United States

Dr. R. H. HEINDEL, director of the American Library of the Office of War Information, has contributed to the May issue of *Agenda* an article "The War and Post-War Integration of Research Activities in the United States", which is of considerable general interest to scientific workers. The article gives a comprehensive picture of the extensive development of decentralized research in the United States, especially in science, to implement the war research programme, and should be read in conjunction with Dr. Karl T. Compton's Pilgrim Trust Lecture (NATURE, May 29, p. 601). The integration of Federal and non-Federal research facilities is a war problem of the highest importance in view of the limited number of specialists and the need for protecting the nation's research structure, now and in post-war reconstruction. The Federal Government has for many years been developing, with all kinds of responsible research agencies, patterns of procedure and co-operation which have proved useful during the War and should not be without value in considering the organization of research in Great Britain and in the British Commonwealth, and particularly the relations between Government research institutions and the universities. The types of investigation suitable for 'farming out' or contracting are almost unlimited. Contracting for research and co-operative programmes depend on the existing personnel, the fields of study, the nature of the problems, the structure of the official and private agencies and the community of agencies willing to serve the nation as a whole, and success here requires more coherence and direction in the formulated needs of the Government. Government demands for certain types of research may encourage within the universities and elsewhere a greater use of inter-departmental and inter-disciplinary approaches to research projects.

In regard to detail, Dr. Heindel refers to an impressive programme of research development and the most extensive use of contracting with substantial funds, centring about the Office of Scientific Research and Development, within the Office for Emergency Management, to which are attached an Advisory Council, the National Defence Research Committee and the Committee on Medical Research. One of the most successful contracts exists between the Public Roads Administration and the National Research Council for the Highway Research Board, while the U.S. Office of Education has also stimulated and participated in numerous co-operative research projects with State and private agencies. The Bureau of Foreign and Domestic Commerce has been extending its co-operation with university schools of business and departments of economics, and acts as a clearing house for business and economic research. Moreover, in the use it makes of the results of scientific study in its legislative duties and in its responsibility as the appropriating authority for the Federal research programme, Congress occupies an important place in the research structure of the nation. In this article, Dr. Heindel's map of research in the United States is not always as clear as it might be, but he indicates the right questions to which answers must be forthcoming if the machinery for co-ordination, for co-operation and contracting is to be used with success and the results of research conveyed to the proper people.

"Abstracts from Cancer Research"

THE problems of the nature and possible treatment of malignant disease are studied in many laboratories and results are published in different journals. It is difficult for any worker to keep in touch with all the published work. Excellent summaries of papers were published for many years in the *Cancer Review*, the publication of which was unfortunately suspended about ten years ago. Since then abstracts have been available in the *American Journal of Cancer*, which has now been replaced by *Cancer Research*. The "Abstracts from Cancer Research" are published separately and the first volume covers the year 1941. The summaries are grouped under the main headings of experimental research (including carcinogenic compounds, hormones, viruses, genetics, physical factors, radiation, chemosurgery, biochemistry and nutrition—chemotherapy, immunology, leukæmia, transplantation and tissue culture), comparative oncology, clinical and pathological reports, statistics and cancer control and public health. The production seems admirable and should be of great value to cancer research workers. This new journal is published in America by the International Cancer Research Foundation, but Prof. E. L. Kennaway and Dr. W. E. Gye arrange for the abstracting of articles appearing in publications in the British Commonwealth.

Laryngology and Folk-lore

IN a recent paper (*J. Laryng. and Otol.*, 57, 527; 1942) on this subject, Dr. J. D. Rolleston states that up to the time of Morgagni (1682–1771), who described several cases in which it was diseased, the larynx occupied a very subordinate place in pathology, its existence being almost ignored by ordinary students of medicine. On the other hand, there are several references in classical antiquity to popular methods of dealing with diseases of the throat, as can be seen by references to them in Celsus, Pliny, Marcellus Empiricus and Julius Modestus. In the Middle Ages a combination of folk-lore with orthodox practice is illustrated by the fact that Aetius of Amida (fourth century A.D.) recommended that after other methods had failed to remove a foreign body from the throat it should be invoked in the name of St. Blaise, the patron saint for diseases of this kind, "to come up or go down". In the eighteenth century, numerous popular terms, especially in Scotland, were given to a special form of laryngitis occurring in children, such as 'croup', 'croops', 'chock', 'stuffing' or 'rising of the lights'. As in the case of many other diseases and morbid conditions, folk-lore has only a few prophylactic measures compared with curative treatment, while its therapy can be grouped under animal remedies, plant remedies, patron saints and miscellaneous remedies.

Earthquakes Registered in New Zealand

DURING April 1943, eleven strong distant earthquakes were registered by the seismographs at Auckland, Arapuni, Christchurch, Kaimati, New Plymouth, Tuai and Wellington, New Zealand. The earthquake of April 6 registered at most of the New Zealand stations occurred at 16h. 07·1m. U.T. near latitude 32° S., longitude 70° W., according to the U.S. Coast and Geodetic Survey. This is mid-way between Illapel and Mendoza in Chile. The earthquake also registered at College, St. Louis, Ottawa, Sitka, Georgetown and fourteen other stations sending records to Washington. The earthquake of April 9 occurred at about 8h. 48·8m. U.T. from an epicentre as determined by the U.S. Coast and Geodetic Survey near latitude 19° N., longitude 145° E., which is in the Pacific Ocean west of Agrigan Island, one of the Marianas Islands. In this case the depth of focus was near 100 km. Additionally, twenty-nine local earthquakes and earth tremors were recorded. Five of these shocks reached intensity V on the modified Mercalli scale. The first, on April 6, was felt in the Wairoa region; the second, also on April 6, was felt near Hawkes Bay; the third, on April 7, was also felt near Hawkes Bay; the fourth, on April 15, was felt over the southern part of North Island, while the fifth, also on April 15, was felt at Manawatu and Wairarapa.

Food Situation in Sweden

ACCORDING to the *Anglo-Swedish Review* of July, comparison of Sweden's rations with those of foreign countries seems to show that the Swedish rations are surprisingly small. Three important products, however, namely, milk, potatoes and other vegetables, are not rationed but can be bought in unlimited quantities. Temporary visitors to Sweden who eat their meals at restaurants may think the food situation is more favourable than it really is. In a restaurant coupons are only required for butter, bread, most of the meat products and eggs. On the other hand, for Swedish households the coupon-free meat products play a very minor part, and their price is so high that they are almost beyond the reach of most consumers.

Space Heating

FOR his chairman's address to the Installations Section of the Institution of Electrical Engineers, R. Grierson took the subject of "British Climate and the Space-Heating Engineer" (*J. Inst. Elec. Eng.*, 90, Pt. 1, No. 29; May 1943) in which the means of assessing the thermal performance of space-heating installations on a rational basis rather than on the present empirical one are indicated. The address first reviews the basic factors involved in space-heating problems, then proceeds to discuss the internal temperatures required for maintaining the desired standard of thermal comfort, external temperatures, and temperature difference and degree-days. The address is printed in abstract in the *Journal*, but the complete text may be referred to in the Institution Library.

Utilization of Small Coals

THE British Coal Utilisation Research Association is arranging a conference on November 10 and 11 to discuss the problems related to the utilization of small coals with particular reference to the results obtained by the users of these fuels. It is known that a great body of valuable experience on the subject exists, and it is hoped, by means of the Conference, to make this experience available to those concerned, and by discussion to direct attention to the most practical and effective methods of utilization. The Conference has the full support and approval of the Fuel Efficiency Committee. There will be three sessions: November 10, at 2.30, on utilization of small coals and slurries; November 11, at 10, on utilization of fuels of high inert content; November 11, at 2.30, on the upgrading of fuels. Offers of papers for discussion at the Conference should be sent to the Conference Secretary, B.C.U.R.A., Rickett Street, West Brompton, London, S.W.6. The Conference will be open without charge to all interested, by tickets obtainable from the Conference Secretary. Papers will be circulated in advance and the proceedings confined to a discussion of the papers.

Searle's "Experimental Optics"

DR. G. F. C. SEARLE writes that additional accommodation for students attending the Cavendish Laboratory, Cambridge, has been obtained in the Geological Museum, and the task of transferring the optics class to that Museum has begun. Dr. Searle's "Experimental Optics", which is required for the course contemplated, is out of print, and Dr. Searle asks former pupils to offer copies of this book which they may have retained to the Laboratory. Letters should be sent to Dr. Searle before sending the books; the Laboratory will pay 16*s*. for each copy in fair condition.

Colonial Service Appointments

THE following appointments have recently been made in the Colonial Service: J. F. G. Wheeler to be marine biologist, Mauritius; J. C. Eyre, agricultural officer, Tanganyika Territory, to be senior agricultural officer, Palestine; J. Smith, assistant conservator of forests, Nigeria, to be senior assistant conservator of forests, Nigeria; J. E. Taylor, assistant conservator of forests, Nigeria, to be senior assistant conservator of forests, Nigeria; R. C. Burgess, lands officer and senior surveyor, Sierra Leone, to be director of surveys and lands, Sierra Leone; W. Harrison, surveyor, Nigeria, to be senior surveyor, Gold Coast.

Measurement of Anomalous Viscosity by the Capillary Tube Method

CAPILLARY tube viscometers have been in constant use over the past twenty years or so, for measuring the viscosity of a wide range of materials such as, for example, clay and flour suspensions, cream, honey, grease, paints, starch pastes, tar, etc., which are not true liquids[1]. The instrument usually takes the form of a Bingham plastometer (Fig. 1 *a*), an Ostwald viscometer (Fig. 1 *b*) or some modification of these types[2-6].

With the Bingham plastometer, an excess air pressure is usually applied above the surface of the material contained in the vessel *V*, thus forcing it through the capillary *C*, the pressure being measured by some form of manometer connected to *M*. If necessary, a correction is added to this pressure to allow for the hydrostatic head of liquid. Considering this viscometer as flow through two tubes of different bore, one large and the other small (radius R and r) and taking l as the length of the capillary and L the (mean) height of liquid in *V*, and if the pressure drop across *V* and *C* is denoted by P_v and P_c respectively, then

$$P_v \propto \eta L/R^4 \quad \text{and} \quad P_c \propto \eta l/r^4,$$

where η is the viscosity of the liquid. These expressions, which follow directly from Poiseuille's law, are valid for a true liquid since η is a constant. In practice, the dimensions of the apparatus are such that, with a true liquid, P_v is negligible compared with P_c and the calculations involved assume this to be the case.

For an anomalous liquid, however, these expressions for P_v and P_c are not necessarily valid, since η can no longer be regarded as constant; we then have

$$P_v \propto \eta_v L/R^4 \quad \text{and} \quad P_c \propto \eta_c l/r^4,$$

where η_v and η_c are the apparent viscosities (calculated from Poiseuille's equation) in the vessel and capillary respectively. Thus for liquids which show a decrease in apparent viscosity with increasing shearing stress or rate of shear (and such materials are fairly common), η_v may be very many times greater than η_c, since the rate of shear in the vessel is much lower than that in the capillary. It is clear, therefore, that under certain conditions it might be possible for P_v to become large compared with P_c, and since pressure, measured in the manner described, is $(P_v + P_c)$, an error would occur in the calculated value of apparent viscosity, the corresponding correct pressure being, of course, P_c. In other words, the apparent viscosity would not be measured solely in terms of the capillary, but would also depend on the relative dimensions of the capillary and vessel.

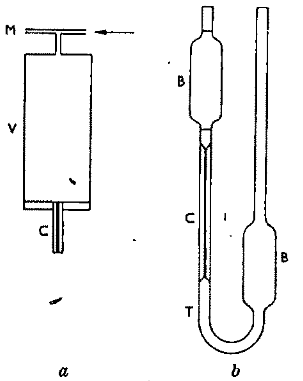

Fig. 1.

		R	L
+,	Capillary No. 1,	$0{\cdot}0238_1$	$3{\cdot}73_5$
□,	,, 2,	$0{\cdot}0417_5$	$3{\cdot}81_5$
●,	,, 3,	$0{\cdot}1871$	$9{\cdot}60_1$

Fig. 2.

The same reasoning can be applied to the Ostwald viscometer, and we find that for materials of the type mentioned, apparent viscosity is obtained not only with reference to the particular capillary, but also to the relative dimensions of the capillary, the two bulbs *BB*, and the connecting tube *T*.

Since most measurements of this kind have been made with types of apparatus similar in principle to those shown, it would appear that this error in pressure measurement might explain many perplexing results published on this subject.

Arveson[7], who measured the viscosity of greases, mentioned this source of error, but did not appear to realize its full significance. However, he eliminated this difficulty in a novel way by recessing the capillary into the vessel, the bottom of which was made a mercury bath to which the manometer was connected. Curves obtained in this way, which show agreement between different capillaries, are given in Fig. 2.

The magnitude of the error involved will depend on the relative dimensions of the apparatus and the form of the viscosity–shear curve of the material. A numerical example, deduced for the Bingham plastometer, will show the order of the error likely to occur. For simplicity let $L/l = 10$ and $R/r = 10$, and assuming an arbitrary rate of shear (taken by Arveson to be $4Q/\pi R^3$, where Q is the quantity flowing per second in a tube of radius R) of 1,000 sec.$^{-1}$ in the capillary, that in the vessel is then 1 sec.$^{-1}$. Taking a representative curve from Fig. 2 (No. 0 cup grease) it follows that $\eta_c = 3$ poises and $\eta_v = 800$ poises and hence $P_v/P_c = 0{\cdot}27$. Thus the apparent viscosity determined in the usual way would be 27 per cent greater than the correct value. This error would be reduced if the rate of shear in the capillary were very high or very low, since for this material the viscosity curve tends to flatten out at the two extremities.

It follows that (unless the material exhibits an extremely rapid drop in viscosity with increasing shear) for a given vessel the smaller the capillary bore and the greater its length, the smaller will be the apparent viscosity. This anomalous variation with radius (and length) is precisely that found by many investigators, and it is usually referred to as the 'sigma' phenomenon. Various explanations have been offered to account for this effect[2], all of which attribute it to a property of the material. Thus Ambrose and Loomis[6] suggest that it is due to thixotropy, while Dix and Scott Blair[8] claim to account for it by assuming that the streamlining layers are not infinitely thin. Other authors attribute the effect to slip at the tube wall.

It is not suggested that the 'sigma' phenomenon is wholly due to this error inherent in the viscometer, but it seems likely that in many instances both effects are present simultaneously. It is possible that in some cases apparently anomalous results can be completely accounted for by the error described, but it must again be stressed that this error can only occur with materials which show a fall in apparent viscosity with increasing shear.

This instrumental error has been eliminated in measurements made recently[9] on rubber solutions and soap-thickened mineral oils using a simplified form of Arveson's viscometer. The results show that for these materials, *provided the capillary is sufficiently long*, thus reducing the 'equilibrium length' to a negligible fraction of the whole, the viscosity – shear curve is independent of capillary size.

Alloys of Gold with Alkali Metals

IT has previously been suggested that gold alone among the heavy metals of the first column of the periodic system forms alloys with alkali metals of definite and simple stoichiometric ratio. Matthewson[1] derived from his experiments a formula $NaAu_2$; Zintl[2] mentioned the formation of NaAu. The discrepancy between these results is probably due to the fact that in the work of both authors oxidation or other unwanted reactions of the alkali metal were not excluded.

For the investigation of alloys of alkali metals with antimony and bismuth[3], I used a simple method to determine the composition of such alloys, which had the advantage that the alloy was formed in high vacuum, thus avoiding contamination of the alkali metal. The procedure, which has been described in detail elsewhere[4], was as follows. A known quantity of the heavy metal was evaporated on to the wall of an evacuated glass vessel. Then the alkali metal was distilled on to this metal layer until, even at the highest temperature compatible with the vapour pressure of the alkali metal, no more metal was absorbed. Finally the amount of alkali metal consumed was determined.

Using this method, I have now investigated copper, silver and gold in combination with sodium, potassium, rubidium and cæsium. The experiments confirmed that no definite reaction takes place with copper or silver. They further showed that the gold layer at first quickly absorbs the alkali metal, but during continued distillation the alkali metal is suddenly deposited as a distinct separate layer on top of the alloy layer. Determination of the amount of alkali metal used to 'saturate' the gold layer indicated that all the alloys correspond to the formula Au*M*, where *M* denotes the alkali metal. The accuracy of the experiments was only of the order ± 20 per cent. owing to the difficulty of measuring small quantities of alkali metal, but this accuracy is sufficient to exclude all simple formulæ other than Au*M*. To disprove the rather improbable possibility of a complicated formula, the experiments would have to be repeated with larger quantities of the metals; this would require larger vessels to avoid excessive thickness of the layers.

As was to be expected, the alloys of the Au*M* type are photo-electrically sensitive, but the sensitivity is too low to be of practical importance. An interesting optical property of the alloys is that, like the $SbCs_3$ alloy[3,4], they show no metallic lustre, and their absorption of visible light, in particular near the red end of the spectrum, decreases from sodium to cæsium. The visual change from a practically opaque gold layer to the extremely transparent AuCs layer is particularly striking.

Urease Activity and Ascorbic Acid

WITH reference to Mr. Elson's observation[1] that ascorbic acid at low concentrations inhibits urease activity, and that this inhibition disappears in the presence of cysteine, it is worth noting that certain polyhydric phenols, for example, catechol and quinol, also exert at low concentrations (one part in two millions) highly inhibitory effects on urease activity, this inhibition disappearing in presence of thiol compounds such as cysteine[2]. It has been shown that the inhibition in this case is due, not to the phenol, but to the corresponding oxidized product, that is, the quinone present in solution with the phenol. The alleviating action of cysteine is due to the reduction of the quinone to the inert phenol. It may be suggested that, in an analogous manner, the toxicity of ascorbic acid in dilute solution is due to the oxidized form of ascorbic acid, namely, the diketone, present in solution, and not to the ascorbic acid itself. The effect of cysteine will be to reduce the dehydro-ascorbic acid to the inert ascorbic acid, a phenomenon which is known to take place, as shown by Crook[3].

Manganese Deficiency in Oats

The value of the water culture method for the study of the role of particular chemical elements in the nutrition of higher plants is generally recognized, and the more exactly the chemical constitution of the culture solution is controlled the more effectively can the study of trace elements be undertaken. By using the water culture technique of Stout and Arnon[1], I have produced the typical symptoms of grey speck disease in oats attributed to manganese deficiency only four weeks after sowing, as well as evidence that this technique will prove valuable in studying the physiological importance of other elements. The method, not previously used by workers in Great Britain, so far as I am aware, involves the use of: 1, 'Pyrex' or 'Hysil' glassware; 2, re-distilled water[2]; 3, specially purified solutions[1]; and 4, the diphenylthiocarbazone colorimetric test[3] for metal impurities in water and nutrient solutions.

In my experiments the culture solutions were prepared according to Arnon[4]. The major nutrient elements (potassium, phosphorus, nitrogen, calcium, magnesium) were added to all cultures. The micro-elements were used in two groups: (1) *A*3 containing copper, boron, zinc, and (2) *B*7 containing aluminium, molybdenum, titanium, vanadium, tungsten, nickel and cobalt. The experiment was designed to show the effect of the *A*3 and *B*7 groups of trace elements alone and together in the presence and absence of manganese. Iron as ferric tartrate was added to all the cultures every week.

The oat grains were germinated over water at laboratory temperature and a week later the seedlings were transferred to the culture solutions in an unheated greenhouse. Fourteen days after this transference, the first signs of manganese deficiency appeared in one of the plants receiving only the *A*3 trace elements. This plant had three leaves and a slightly yellowish-green appearance, and about halfway along the third leaf a grey-green spot had appeared, at which point the leaf had bent over sharply. Seven days later, twenty-one days after planting, ten out of fourteen plants (three of which had died) growing in manganese-deficient culture solutions were showing the typical break on the third and/or fourth leaves at oval grey-green spots. These grey specks soon dried up and became yellow-brown. These symptoms appeared on plants in the culture solutions containing, as regards micro-elements: (1) the *A*3 group only, (2) the *B*7 group only, and (3) the *B*7 and the *A*3 groups. No typical grey speck symptoms as described above appeared in the fourteen plants grown in the presence of manganese.

The effect of the other trace elements was seen to be similar in the cultures with and without manganese. The best plants as regards growth and greenness, in the series without manganese, were those receiving the *B*7 and the *A*3 groups, the next best were those receiving the *B*7 group alone, while the worst were those with the *A*3 group only. The series with manganese showed the same general effect but were in all cases better plants. These observations were substantiated by determining the dry weights per plant in each kind of culture, as shown in the accompanying table.

The conclusion to be drawn is that one or more elements of the *B*7 group are probably essential for the growth of oats in addition to the four generally recognized trace elements manganese, zinc, boron and copper.

Micro-elements added	Average dry weight in gm. of oat plants four weeks old	
	With Mn	Without Mn
*A*3	0·101	0·095
*B*7	0·161	0·130
*A*3 + *B*7	0·238	0·127

This finding for oats is similar to that previousl indicated by Arnon in regard to the elements necessary for lettuce and asparagus.

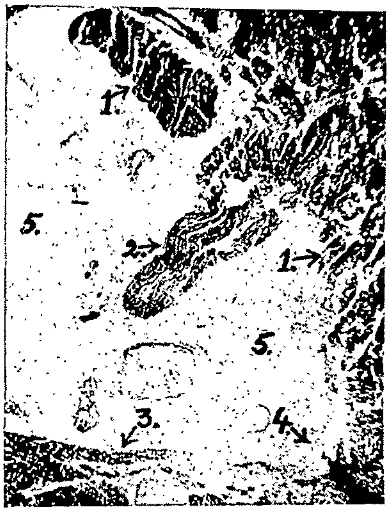
Etiology of Paroxysmal Tachycardia

At autopsy in a case of paroxysmal tachycardia a muscle bundle was found connecting the lef auricle with the left ventricle. In between attacks this case showed an electrocardiogram with shortene *PQ* interval and a slowly rising initial part of th *QRS* complex. This bundle may have been the caus of the disease[1]. The bundle, being more than half centimetre long in its free portion, was visible to th naked eye in microscope preparations. This structur is entirely different from the structures at the *A* border, described by Kent at the end of the las century.



1, left auricle; 2, part of the bundle; 3, left ventricle; 4, annulus fibrosus; 5, fat tissue.

Of further interest is the fact that one sister an three brothers of the deceased also suffered fro paroxysmal tachycardia. One of the brothers di closed a similar electrocardiogram; he had a typic Wolff-Parkinson-White syndrome.

The Pattern of Youth: an Interim Report

This report, which is really part of a general survey covering dentition, dietary and physical traits in the public schools, deals with provisional conclusions on the effects of war-time rationing on the relative stature and weight of more than 3,400 boys and girls attending the public schools in England and Wales, Northern Ireland and Eire—this last being added as a control since rationing has not been as stringent there as in the United Kingdom.

If it is agreed that superior physique, immunity from disease, courage, ambition, local and national tradition, home influence and energy are the qualities required for success in life, then nowhere can they be found more equitably adjusted than among the economic classes whose children attend the great public schools.

A study devoted to them is one of the principal means of assessing the improvement or physical deterioration of the race.

The conclusions arrived at may be broadly stated as follow: (*a*) that war conditions have had, up to December 1942, no deleterious effect on the stature and weight of the youths in the public schools; (*b*) that they have on the contrary increased the physique of youth in the countries under survey; (*c*) that English boys in the age-groups of 13, 14, 17 and 18 exceed in height and weight the corresponding ones in Eire. The age-group 15 in England are of the same height but weighs more than the corresponding group in neutral Eire; however, the 16-year-olds in Eire are taller but weigh less than their age-group in England. Northern Irish boys in all the age-groups but one, namely, 14, weigh more than their fellows in Eire. The 14- and 18-year-olds are taller than, and the 17-year-olds are as tall as, their corresponding age-groups in Eire; (*d*) with regard to girls the results are not so conclusive, but from the age of 14–18 Eireann girls tend to weigh more than their age-groups in England, Wales and Northern Ireland.

In every instance all the boys and girls in the countries under survey have exceeded the normal height and weight for their ages as given by Quételet or that given for Anglo-Saxons by Dr. Bruce Williamson.

The accompanying tables show the average increase per age-group, as contrasted with the pre-war normal for the English-speaking nations (p. 279 of B. Williamson's "Handbook on Diseases of Children, 1936").

I wish to express my thanks to the principals, headmasters and headmistresses of the following schools in England: Rugby, Repton, King's College (Taunton), The Abbey School (Malvern), Ch. Edward Brooke's (London), Chelsea Polytechnic, Liverpool Training-College, Felixstowe College, Bishop Blackall's (Exeter), Notre Dame Collegiate (Liverpool). In Wales, Howell's School (Denbigh), Howell's (Llandaff and Cardiff). In Northern Ireland, Londonderry High School, Collegiate School for Girls (Enniskillen), Technical High School of the College of Technology (Belfast), Coleraine Academical Institution. In Eire, St. Columba's College (Rathfarnham, near Dublin), High School (Sligo), Celbridge Collegiate School (Co. Kildare).

I also wish to thank Miss Spafford, of the Ling Physical Education Association. Without the active and wholehearted co-operation of them all in these days of depleted staffs, this work would have been impossible.

R. E. G. Armattoe.

Overlapping Abstract Services

In the article "Co-operation in Scientific Research in the British Empire" in Nature of July 10, reference was made on p. 30 to the inquiry which has recently been addressed to members of the Society of Dyers and Colourists, in connexion with the abstracts which appear in the Society's journal. This inquiry was prompted not because of any doubts as to the value of the Society's abstracts service, but by heavy demands on the Society's available space for original matter, and a desire to ensure that the Society's limited supplies of paper during the War were being used to the best advantage.

Of the replies received from members, so many stressed the vital importance to them of the Society's abstracts, which are more detailed, if less comprehensive in their scope, than those available otherwise, that it has been decided it is imperative that they be retained.

A number of our members are in favour of a centralized abstract service; and there is no doubt that the Society would be very glad to discuss this matter with other interested bodies.

James S. Ridsdale.

Research and Planning

In the leading article in Nature of August 7 reference is made to my paper "The Autonomy of Science"[1], and the comment is made: "it is, to say the least, unfortunate that he should impute to the type of planning and organization of scientific effort and resources urged by Sir Stafford Cripps an attempt to interfere with the internal discipline of science and the decisions leading to discovery". My paper was printed before Sir Stafford Cripps made his statement of policy. It contains no criticism—much less a rejection—of such policies, which follow the lines established throughout the world, including Great Britain, for at least a generation. Sir Stafford's plans seem in fact entirely admirable to me.

What I criticized were the views concerning the nature of science and the place of science in society which were recently advocated once more by some of the more influential speakers at the January meeting of the Association of Scientific Workers. "Then research will not be conducted for itself, as an end in itself"—was stated in an authoritative summary of the aims set by that meeting[2].

I am not concerned primarily with the future effect of these principles in Great Britain, the great civic tradition of which may protect her indefinitely from their ill effects. Nor would I wish to intervene in this respect. What I am concerned with are these principles themselves, and the prospect of seeing them spread on the wings of Allied victory all over a dislocated world, helping to destroy even further the ideal—which I hold to be essential to our civilization—of scientific truth pursued and upheld for its own sake.

University,
Manchester.

Future of Technical Colleges

Messrs. Barrer and Andrews have referred[1] to the very important question of the training of students in technical colleges for external degrees, which is raised in the Institute of Physics Report on "The Education and Training of Physicists". Their interpretation of this Report as hoping to relieve the technical colleges of the necessity of preparing students for external university degrees is not perhaps quite fair to the carefully considered wording of the Report. The Report does not deny, or imply, the right of the technical college to give the highest training to the young technologist or to transfer the higher flights of technology to the universities. The actual wording of the Report reads: "It is desirable that the distinction between the functions of the Universities on the one hand and of the Technical Colleges on the other should be clearly recognized and that the Technical College should not be deflected too much from its own important field by the necessity of training students for External University Degrees", and concludes that the training for such degrees should not be a primary function of a technical college.

I am sure that no educationist will disagree with Messrs. Barrer and Andrews in their view that Great Britain requires a number of technological institutes capable of carrying out technical studies to the highest grades, including the creative work of research departments and, it may be added, 'cultural' studies and recreational activities as well. It is not right, however, that the coaching of a relatively few people for examinations run by an outside body, which body dictates a syllabus and a standard with little or no regard to methods of training and opportunities for social development of the individual students, should come to be regarded as the highest function of a technical college and should unduly influence its educational aim.

A planning committee such as that of the Institute of Physics is working in the realm of *educational ideals*, and it is therefore appropriate that it should review the existing provision of university courses in the sciences in order to determine what arrangements may be made so that all those capable of benefiting from a university course may be provided with full facilities for a proper university education. Degree courses in technical colleges are makeshift courses, and have grown out of a makeshift system designed for a period when (1) few universities existed in Great Britain, and (2) the cost of university courses was almost prohibitive for the average individual. While acknowledging their value in the past, and admitting their possibilities to a limited extent in the field of adult education, we may well doubt whether external degrees are adapted to form a serious factor in modern technical education.

Many technologists would prefer to see the larger technical colleges capable of carrying out education and training to the highest standard based on technical subjects, and awarding their own diploma, which should be comparable with a university degree. The courses in such colleges would be complementary to those of the universities, and some university graduates would by arrangement proceed to such colleges for their post-graduate technical training after having completed their degree courses at the university. Then again, within the technical colleges, at a lower level, the National and Higher National Certificate schemes are capable of further development (even on present lines) and should be extended to cover the newer industries, for example, plastics, radio and production engineering, etc. Indeed, there seems no limit to what the technical colleges might achieve in their own particular sphere without duplicating courses which can in general be done much better in the universities.

I feel that the technical colleges are in grave danger of losing their way. At one end of the scale they are flirting with what is essentially secondary school work, at the other with university education, while tending to neglect their most important work, which lies between and covers both full-time and part-time courses up to the highest level of achievement, of a character most in accordance with the needs of the 'real' world, together with the vast field of adult education, cultural, social and spiritual values not being neglected on the way—the whole constituting a 'people's university' in the fullest sense of the term.

Never before has the technical college been such a centre of popular interest in Great Britain as it is to-day—thanks to the opportunities it has had of serving national war-time needs. We who are engaged in this work have surely no longer any need to preach the importance of technical education as had our predecessors, Huxley, Roscoe, Thompson, etc. We failed to take advantage of two previous opportunities to put technical education on a proper footing, namely, in 1889 and 1902. Let us, therefore, not cast away our new opportunities which are on the rising tide, by yielding to the specious attractions of external degrees. We have all to gain and nothing to lose by leaving the universities to do their own particular work (even if it does include what we have come to regard as technological subjects). The technical colleges will best serve the community by developing their special field, which is determined by industry, commerce and the professions, without the restraint of external degree examinations. Nevertheless, it is not desirable that the technical colleges should pursue an isolationist policy, but rather that they should work in co-ordination with the universities, for only in this way can the activities of each be best directed to the establishment of the ideal educational world.

RESEARCH ITEMS

rigins of Kingsholm, Gloucester

THE movements in Britain of the Second Legion f the Roman forces before it settled at Caer-on have given rise to much speculation. It is ow suggested (Glevum and the Second Legion, art I. By Charles Green. Public Museums, loucester, Occas. Pap., No. 5) that the Legion was stablished at Kingsholm, to-day a suburb lying to he north of the centre of Gloucester, and that later true *Colonia* was founded there to accommodate etired soldiers of the Legion after it had moved to ts permanent home at Caerleon. Furthermore, down y the River Severn, a small quayside settlement rew up which later tended to spread inland from he river. This was the port. It is suggested that n analysis of previous coin and pottery finds, so ar as exact locations can to-day be assigned to them, nd a study of some recent discoveries point to this onclusion. The fact, too, that Ermin Street takes sharp bend at Wotton to arrive at modern Glouces-er, but if continued in a straight line would pass hrough Kingsholm, reinforces the suggestion.

taphylinidæ of the West Indies

THE United States National Museum Bulletin 182 1943) is devoted to a bulky monograph on the above ubject. In the compass of 658 pages the author, ichard E. Blackwelder, has dealt with some 91 enera of these beetles and 468 separate species—xclusive of those included in the subfamily of the leocharinæ. Altogether 6 genera and 212 species re being described as being new. The Aleocharinæ ere omitted for various reasons and chiefly on ccount of the difficulty of recognizing species from nadequate descriptions. It is interesting to note that mong all the species of Staphylinidæ that occur in he West Indies, Cuba has 172 species, Jamaica 128 nd Trinidad 122—more or less proportionate to the ize of those islands. While many more species prob-bly await discovery, this work must be considered as olerably exhaustive for the time being. It was ased on 45,000–50,000 collected specimens: in ddition to these, many others were examined in ublic and private collections. The author specially nentions the co-operation of the British Museum Natural History) in the work of identification. The eys provided are original: there is a full synonymy f all names and detailed specific descriptions are iven, but there is a general lack of illustrations, there eing only three figures in this bulky work. The uthor states that several factors have prevented the se of primary genitalic characters in the descriptions. The first was lack of time to develop the requisite echnique. Another was that some genera do not resent usable specific characters on the genitalia. t is, however, to be regretted that so little has been done on this phase of study for the Staphylinidæ nd many other families of Coleoptera.

ungi from Decaying Alder Leaves

AN interesting and detailed account by C. T. ngold of sixteen unusual fungi growing upon decay-ng alder leaves in a Leicestershire stream has recently ppeared (*Trans. Brit. Mycol. Soc.*, 25, 339; Dec. 942). All the fungi belong to the Hyphomycetes, nd ten are new species within the new genera Margaritispora, Articulospora, Tetrachætum, Tricladium, Alatospora, Lunulospora and Flagellospora. Two new species of the current genus Heliscus have also been found. Structural and taxonomic descriptions of all species are given in detail. The majority of these fungi produce conidia which are branched or have three-dimensional curvature. It is suggested that this structural feature has a survival value in that such spores, borne by the water current after liberation, can readily be entangled by alder leaves submerged in the stream. All except three species have been grown in pure culture on malt agar and oatmeal agar. This somewhat abstruse study nevertheless widens our mycological horizons, and raises important questions of economic ecology connected with the breakdown of organic matter.

Interlocking of Bivalents

S. G. Smith and E. R. Boothroyd (*Canad. J. Res.*, 20, 358; 1943) have made an analysis of the interlocking of bivalents in *Trillium erectum*. In 346 cases of interlocking, there were equal numbers of true and false interlocks, the latter being constituted by one bivalent being inserted between two chiasmata of another bivalent. An interlocked chiasma and chromatid interlocking were observed. The frequency of interlocking is proportional to the length of chromosome arm minus a minimum length. Interlocking reduces the chiasma frequency and would appear to do so by interference with the position at which chiasmata would usually form. The results are discussed in relation to several theories of chromosome behaviour.

Bar-eye Locus in Drosophila

A FURTHER step in the analysis of the position effect at the bar-eye locus in *D. melanogaster* is provided by the discovery of a lethal gene *Eb* by G. Bonnier, M. Nordenskköld and G. Bägman (*Hereditas*, 29, 113; 1943). *Eb* has similar effects to *B* in respect of the expression of position effect upon eye shape. It is situated to the right of *B* and reduces crossing-over in the *X*-chromosome between *B* and *fu*. Cytological studies indicate that the bar segment is not duplicated in *Eb*, but this might be a deficiency. This is, however, unlikely, since a bar/bar-deficiency female has almost normal eyes. The authors therefore suggest that *Eb* is a modifier of *B* within the bar segment and therefore they raise again the question of step allelomorphism and the divisibility of the gene.

Polyploidy and Plant Geography

A. and D. LÖVE (*Hereditas*, 29, 145; 1943) have made a statistical analysis of the frequencies of polyploids in different localities of Europe and Africa. They confirm the view that there is a correlation between polyploidy and latitude. Polyploidy is more common among monocotyledons than dicotyledons. In the Alpine regions of the Pamir, Altai and the Caucasus, the greater hardiness of polyploids is apparent. The preponderance of species in tropical and moderate climates and the low number of species in cold regions is believed to result from the greater adaptability of polyploids to extremes and the greater long-day photoperiodism of polyploids.

Pollen Tetrads in Petunia

H. LEVAN (*Hereditas*, 28, 429; 1942) has discovered a race of *Petunia nyctaginiflora* in which the pollen remains in tetrads after dehiscence. The phenomenon is due to a single recessive gene *t*. Such behaviour may be of value in the analysis of segregation as in fungi and mosses.

Intersexuality in Melandrium

D. Löve (*Hereditas*, 28, 497; 1942) has shown that the *Y*-chromosome of her intersexual plants of *Melandrium rubrum* is different from that of normal male individuals. The *Y*-chromosome of the male is about 7·5 long with a median centromere whereas that of the intersexes is 3·5 + 4·5. The evidence suggests that the "*Y*" chromosome of the intersexes is composed of a normal *X*-chromosome to which a portion of a *Y*-chromosome has become attached. Thus an *XX*-individual with a portion of the strong male determining *Y*-chromosome would probably be such an intersex.

Theory of Chromatography

In chromatography a solution is run through a column packed with a suitable adsorbing material and the solutes deposit on the surface of the material in bands. If afterwards a pure solvent is run through the column the bands move at different rates. The method has found wide applications. D. de Vault (*J. Amer. Chem. Soc.*, 65, 532; 1943) has extended a theory of the process due to J. N. Wilson (1940), which neglected diffusion and non-attainment of equilibrium. Some important results not discussed by Wilson are pointed out. The theory predicts both sharp and diffuse boundaries to the bands formed in the column. Differential equations are set up for multiple solutes, but no general solution is reached. Some evidence is found that here also the boundaries may usually tend to be sharp in front and diffuse in the rear, but the conclusion is not definite. In a typical two-solute case the concentration of the faster-moving solute in the band where it is pure tends to be larger than in the original solution. Some suggestions for further development are made.

Colour of Ferrocyanide Crystals

The colour of alkali ferrocyanide crystals sometimes varies from light yellow to amber. A suggestion that this is due to isomerism has been shown to be incorrect. Another suggestion is that salts such as $K_3[Fe(CN)_5H_2O]$ are the cause of the colour. H. E. Williams (*J. Chem. Soc.*, 223; 1943) has shown that this is not the case with commercial sodium and potassium ferrocyanides, and that the amber-coloured crystals sometimes found in commercial ferrocyanide are caused by the presence of traces of colloidal ferric hydroxide. Methods for detecting and estimating small amounts of the aquo-salt and ferricyanide in ferrocyanide solutions are described.

Busbar Protection

A critical review of the methods and practice of busbar protection is given in a paper read in London recently before the Institution of Electrical Engineers by M. Kaufmann and W. Szwander. The general conclusions drawn from the study are as follows. The high standard of reliability now required of distribution systems greatly enhances the importance of the busbars and demands a correspondingly high standard of performance and reliability in the busbar protective arrangements. Busbar protective schemes are available which attain this standard and can be relied upon not to impair the reliability of any system to which they are applied. The stringent precautions taken to ensure the greatest possible reliability are not an indication that the schemes are not sufficiently reliable in themselves, but are the result of the need for an exceptionally high degree of reliability compared with that of the protection for other elements. Since the selectivity of busbar protection, together with its high speed of operation, constitute its main advantages, it is especially applicable to installations with sectionalized busbars. The application of separate busbar protection lends itself more easily to newly projected plants than to existing installations. It is thus important to give consideration to the possible future application of an appropriate busbar protective scheme in designing new plants. The provision for its future addition should include, for example, insulating the switchgear framework from earth, providing current transformers on both sides of busbar-coupler and busbar-section breakers, etc. Busbar protective schemes must be adapted to the individual needs of the particular case. For the less important installations only relatively simple schemes can be justified economically, but, in general, schemes without some form of 'check' should not be used. Testing facilities should preferably be provided if the scheme is at all elaborate. Though improvements in the existing back-up protection are not a substitute for proper busbar protection, they should be considered in cases where the application of busbar protection is so difficult as to be impracticable.

Photographic Survey of Galactic Clusters

George Alter has discussed the results of a photographic survey of galactic clusters—N.G.C. 6596, 6603, 6605, 6613, 6618, 6645, 6647, I.C. 4725, Tr. 33, Cr. 371, 469, carried out at the Norman Lockyer Observatory, Sidmouth (*Mon. Not. Roy. Astro. Soc.*, 103, 1; 1943). The methods employed have been described in three previous papers. The group of clusters investigated lies within a region which includes most of the small Sagittarius Cloud, and of the eleven star groups which various catalogues record as clusters, it is considered that five are not true clusters. Unfortunately, there is very little convention with regard to including a condensation as a galactic cluster, but in the present case those condensations which have no appreciable concentration and boundary are not considered as galactic clusters and are treated differently from the other six. These other more definitely recognizable clusters presented certain difficulties. The colour index agreed well with the spectral types of their members, but this seemed inconsistent with the fact that these clusters lie within a region where selective absorption has been found, and so some colour excess might be expected. For this reason it must be assumed that the clusters lie in regions where there is little or no absorbing matter, or alternatively, there was a systematic error in the colour index of the investigation. The second assumption seemed much more likely, and it was decided that a systematic error was caused by a wrong photographic coefficient. This error had very little effect on the investigations of clusters which had been previously published, because the zenith distances were small, but in the present cases where the zenith distances are about 70° it is significant. It is suggested that N.G.C. and Tr. 33 contain giants, and a remarkable secondary condensation of ten stars is found in the first of these.

EDUCATION AFTER THE WAR

SOME seventy delegates from twelve different countries attended the fourth general meeting of the Association of University Professors and Lecturers of the Allied Countries in Great Britain, held at New College, Oxford, during July 16–19, which included a conference of the Association of University Teachers. This was the largest and most important educational conference of the Allied Nations yet held in Great Britain, and the delegates were engaged in working out practical methods of post-war education in the occupied countries and seeking collaboration in this sphere with British and international bodies. The conference was welcomed by Sir Richard Livingstone.

At the opening session, at which Dr. S. A. Glaser (president) was in the chair, an address on the history of the University of Oxford was given by Prof. F. M. Powicke, regius professor of modern history at Oxford. Prof. Powicke said that Oxford has never ceased to be a place of debate and controversy. Oxford men have been the pioneers in constructive work for the betterment of the lot of mankind and for the furtherance of a wise imperialism and an international outlook upon affairs. Oxford has always been receptive, and in that it is characteristic of Britain. Now Oxford has to help bind up the wounds of learning but, whatever changes may come, Oxford will insist on being the same. Dr. Glaser remarked that when victory is won, Oxford traditions will inspire and animate university life all over Europe.

On July 17 the conference divided into various sections to discuss such subjects as collaboration with British scholars and with international bodies, reconstruction of science and learning in the occupied countries, post-war education of youth and future collaboration between the universities of Allied Countries in law, science, technology, economy, modern humanities, history, medicine and information for students.

Sir William Beveridge, master of University College, and Lady Beveridge, who have just returned from a visit to the United States, received the members of the conference at University College on July 17, when they gave a brief impression of their visit to America. Sir William said he looks forward to the days when meetings of professors from many countries would be held in every country instead of one or two centres.

Sir Richard Livingstone, president of Corpus Christi College, extending a welcome to the delegates, said that they were welcoming men and women, eminent each in his own branch of learning, ministers of wisdom, knowledge and truth. “But we welcome omething more—a fortitude, endurance and faith in great adversity less often required of scholars, which has not been required of us. We wish to pay homage o that; we hope we shall not forget the example you have shown us; for the exiled scholars of Europe have enriched the history of scholarship with somehing even greater than learning.” The lack of a ommon language and of a common faith, he said, are great obstacles which should be surmounted. “Many stones need to be set into the foundations if he building of international friendship is not to be swept away by the next big flood that comes. Economic agreements, political understandings, personal friendships and mutual intercourse are among them. But these are not enough by themselves. The only mortar that can hold them together is a common faith. Universities absorb themselves in their various specialisms, and ignore the question of conduct and of the beliefs from which conduct springs, as if these were no part of their business. If so, we are ignoring the centre of the problem and gravely limiting our contribution to its solution. I would plead that we regard it as very much our business, and know that I shall plead to sympathetic ears, for it is not your knowledge or your studies that have inspired and sustained you during four black years—it is a spiritual force, a faith.”

Aims of the Association

Dr. Glaser spoke of friends and colleagues in the occupied countries, and said that those present would wish to confirm most solemnly their unity and solidarity with them and to send to those still alive words of sympathy and belief in their liberation. Speaking of the foundation of the Association, he emphasized the encouragement and help they have received from their British colleagues. The Association comprised 249 members and two guests, and now represents seventeen countries. One of their main tasks, perhaps even the reason and justification of their formation, is the reconstruction and rehabilitation of the university life in the occupied and invaded countries when the War ends. A special section has been formed to deal with the problem and is working in close collaboration with the Committee on Post-War Education of the British Association.

The Association's second aim is contact and collaboration with the Anglo-Saxon scientific world. Prof. Glaser spoke of their collaboration with the British universities and said they have met everywhere great friendliness, understanding and hospitality. He mentioned the idea of an international university, an Allied academy of medicine and an international university institute, which would be considered as a centre of university education, with a special information and registration office and a department for comparative education. “If the only result of our present work and endeavour would be the fact that we came together and succeeded in formulating a common basis for collaboration, this one fact would be a remarkable achievement and of far-reaching consequences.”

Maintenance of European Civilization

Dr. Gilbert Murray said they had a common aim that united them far beyond victory in the War and the restoration of national freedom; there is the immense and inescapable task of maintaining European civilization. “We Europeans are trustees for the human race of a great treasure—a treasure built slowly up by the efforts of the human souls in Greece, Rome and Jerusalem, and in the free nations of modern times. People like you and me must see that it is not lost. War is deadly to a civilization like ours. A Nazi victory would utterly destroy it. You and I can do something for the material side, but the intellectual is our special and obvious duty, and I am sure that no intellectual restoration is worth much which does not carry with it a moral restoration as well.”

The White Paper of the Hot Springs Conference on the organization of the agriculture and food supply of the world and the report on the transition from war to peace economy just published by the

Economic and Financial Organisation of the League of Nations, he added, show that, appalling as the post-war condition of Europe is likely to be, the United Nations have means of dealing with it such as have never been equalled or approached in the world before, and, so far as we can judge, the present leaders of the nations are firmly resolved to use them. He reminded his audience that as university teachers of the Allied Nations, they will have great material difficulties to contend against, but he sees no reason to expect such obstacles as would make it impossible for them to carry out their obvious duty—to keep alive the intellectual and artistic culture of Europe.

Post-War Plans

Prof. A. Sommerfelt, in dealing with the future of the Association, referred to the need for maintaining and extending its aims. He suggested that the Association should become an international organization, and that as enemy-occupied countries are liberated university professors and lecturers of those countries should be invited to join. Prof. Sommerfelt also suggested considering the appointment of a permanent secretary and secretariat, and urged the need for linking up with the international educational organizations which will be set up after the War.

The conference considered reports from the various sections which had been at work on the possibilities of setting up an educational clearing house for Europe. The law section was asked to prepare a list of English law books which would constitute a working law library for universities on the Continent. The history section had discussed the possibilities of preparing a handbook of suggestions for teachers dealing with the problems of objective history, a text-book of world history for secondary schools, and a short history of the war, starting from January 1, 1938. The science section particularly emphasized the need for establishing an international body for the collection and co-ordination of information concerning inventions and discoveries.

Prof. Jean Timmermans, of Belgium, was elected president of the Association for the ensuing year.

International University Conference

The members of the Association of University Professors and Lecturers of Allied Countries took part, on July 19, in a meeting of the International University Conference, held under the auspices of the Association of University Teachers. Dr. Gilbert Murray presided.

Prof. Stefan Glaser, Polish Minister to Belgium and Luxemburg, speaking of the Association of the University Professors and Lecturers of Allied Countries in Great Britain as a permanent post-war organization, said they are now trying to elaborate the final statutes of the Association. The Association will probably be transformed in due course into an International Association of University Professors, in order to give colleagues from neutral countries the opportunity of joining the Association as full members. The definite organization of the Association will be postponed until after the War, when their colleagues from the occupied and invaded countries will be able to express their views on the matter. Until then the Association will be open unconditionally to scholars from Allied countries, and its seat will probably be Great Britain.

The Association will endeavour to protect the professional interests of university teachers, an this will be not only in their individual or persona interests, but also, and perhaps above all, in th interests of science and learning, with the object o assuring the most appropriate conditions and atmosphere. It will also deal with all matters and problem of interest and value to the object and aim of thei endeavours, namely, science and research work.

In his opinion a true intellectual solidarity, spiritual understanding based on mutual confidenc and friendship among scholars, is not only the bes pledge for the progress of culture and civilizatio but also for a political understanding, for a wis community of their countries and their people, an therefore for the security of peace and order in th future.

Prof. R. J. Tabor (Great Britain) introduced proposal, which was agreed to, that the reconstructe International Association should function as a clearing house and an information centre on universit affairs. Another proposal, that it should be a functio of the International Association to safeguard th freedom and professional status and interests o university teachers, introduced by Prof. S. Brodetsk (Great Britain), was carried.

An International Institute

Agreement was also reached on a further proposa that the International Association be invited to tak over the functions of the International Universit Conference. This proposal was introduced by Pro R. C. McLean (Great Britain), formerly secretary o the International University Conference.

Prof. Stefan Glaser introduced a proposal that th International Association should be asked to tak steps towards the creation of an International University Institute. The Institute would serve as a information and registration centre and would dea with such problems as exchange of teachers, exchang of students, research work in foreign countries, programmes of studies, inter-validization of diploma standard text-books and international congresse and conferences. It would also, he suggested, hav a school of comparative education, the aim of whic would be the facilitation of specialization and th provision of experts to the respective universities.

This proposal was also agreed to, and the conference than expressed its general approval of th constitution and aims of the proposed Internationa Association of University Teachers.

An International Language

The conference concluded with comments on som factors which hinder the development of internation relations, and Prof. A. Sommerfelt (Norway), speakin of the language difficulty, said the future internation organization of university teachers ought to dra the consequences of the events they were passin through. It ought to recognize only English an French as its official languages.

Prof. J. Timmermans (Belgium) agreed that th English language would play an important part i the future, but felt that it is essential to go ahea with research work with a view to the creation of a artificial international language. International trad and scientific intercourse require a language which simple as well as precise and invariable. An artifici language is as necessary in that connexion as th notes used for music.

NEEDS OF LOW-INCOME FAMILIES*

A SUB-COMMITTEE of the Aberdeen Branch of the Children's Nutrition Council has made a survey in response to a suggestion of the Director of Education for Aberdeen that local authorities, having the power to provide free meals out of public funds for necessitous school children, would find it very useful if some standard by which to judge 'necessity' in every particular case could be made available. It may be of interest to mention that such a standard was approved by the Board of Education and has been in use for the last three years in Chester. It was designed by the present writer for the Chester Education Committee, and its purpose was to determine appropriate maintenance allowances to be paid in respect of children awarded special places in secondary schools, taking into account the size of the family income. Each case was previously dealt with on its merits, and some gave rise to a good deal of discussion and consequent waste of time. Now, all are settled automatically by reference to an objective scale of income needs. There is no doubt that such scales will in due course be adopted generally throughout Britain. They are obviously more scientific than the prevailing methods of assessment, which mostly take into account only the available income per head and aim at keeping grants below an agreed limit selected on no very rational basis.

Assuming payment of rent and rates or taxes has been made out of income, what is the minimal net balance needed for the adequate maintenance of any given family ? That, in essence, is the question to which those who made the Aberdeen survey sought an answer. It will be noted that it is virtually the same question as that Sir William Beveridge had to consider in framing the allowances, under his Plan for Social Security, to be paid to families in want due to the cessation of earnings or some other cause. It will therefore be of interest to compare his estimated figures with those proposed as a result of the Aberdeen inquiry.

Those who are at work on such problems should always bear in mind also the results of the analysis of a random sample of nearly 9,000 weekly budgets of households, living in industrial areas, collected by the Ministry of Labour in 1937–38. These budgets give authoritative information about the actual expenditure of working-class families, and can be accepted as more widely representative than the figures which result from any purely local inquiry. They provide an invaluable check on estimates of the minimal necessary expenditure of low-income families in a particular area.

The Aberdeen Branch of the Children's Nutrition Council found that the cost of a suitable diet for a moderately active man in August 1942 was 8*s*. 9*d*. a week. This is one of the key figures used in the Aberdeen survey. To translate 'persons' into 'standard' men, each person less than fourteen years of age was given a man value of 0·65, while each person of fourteen years and more was reckoned as one, irrespective of sex. This is a second key figure in the inquiry. Nearly two thirds of the thirty families investigated spent 45–60 per cent of their available income on food (available, that is, after deducting rent and taxes). Accordingly, 55 per cent was taken as the ratio which expenditure on food normally bears to available income in families with small incomes and two or more children to support. This is a third key figure in the inquiry, for it is thence assumed that the basic minimal income per man value per week should be taken as $\frac{100}{55}$ of 8*s*. 9*d*., or 16*s*., for this type of family.

In the Beveridge Report it is stated that it would have been possible, at 1938 prices, "to provide an adequate dietary, either on the scale laid down in the 1936 and 1938 Reports of the Technical Commission on Nutrition by the League of Nations or on the scale laid down in 1933 by the Committee on Nutrition of the British Medical Association, for a man and woman together at a cost of about 13*s*. a week". This, Sir William Beveridge suggested, could reasonably be subdivided : 7*s*. for a man and 6*s*. for a woman. The corresponding average figure for a child, on the League of Nations dietary, he put at 5*s*. 11*d*. Allowing for the change in prices since 1938, the Beveridge food standard becomes about 8*s*. for a man, 6*s*. 10*d*. for a woman and 6*s*. 9*d*. for a child in August 1942 ; whereas the Aberdeen standard at that date is 8*s*. 9*d*. for a man or woman and 5*s*. 9*d*. for a child. When the two standards are applied to a family of husband, wife and three children, the Beveridge standard provides 35*s*. 1*d*. and the Aberdeen standard 34*s*. 9*d*. for the purchase of food. Compensation is thus made for the rather high allowances given in Aberdeen to each parent—when compared with the League of Nations standard as interpreted in the Beveridge Report—by the rather low allowances given to the children.

According to the Ministry of Labour budgets, 46 per cent of the average net expenditure per household (after subtracting the average amount spent on rent and rates) was accounted for by food in 1937–38. But these families included many in good as well as in poor circumstances, so that the 55 per cent taken as the corresponding proportion in Aberdeen for low-income families does not seem unreasonable. For the present purpose the average budget expenditure may also be taken as a rough guide to the minimal cost of household and personal sundries. If, at a guess, one third of the actual average budget expenditure, say, 8*s*. 6*d*., is accepted as a reasonable minimum allowance for a family with three children, and account is taken of the rise in prices by August 1942, we have the following estimate deduced from the average budget family figure : 12*s*. 10*d*., as compared with 13*s*. 6*d*., the Aberdeen allowance. For clothing, and fuel and light, the Aberdeen scale for the same family may be more fittingly compared with the standards used by Sir William Beveridge, although these are really based also on the budget figures. Allowing for price changes, the figures are 9*s*. and 6*s*., respectively (Aberdeen), and 10*s*. 7*d*. and 6*s*. 4*d*. (Beveridge).

Several important points are stressed by the authors in the account they give of this survey. There is no space left to comment upon them here, but the hope may be expressed that the report will be widely studied by representatives of local authorities who are closely concerned with the problems raised, and that they will be encouraged thereby to adopt suitable scales for their own areas. Such scales should, of course, be revised periodically to allow for price changes and, possibly, generally improving standards of living. This is done once a year in Chester.

D. CARADOG JONES.

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

ANNUAL CONGRESS

THE South-Eastern Union of Scientific Societies held its forty-eighth annual congress at Reading on July 24, a single day of sessions attended by eighty representatives and members, a number above average for such war-time congresses.

A representative assembly to transact the business of the constituent societies was held in the Abbey School, at which C. E. N. Bromehead of the Geological Survey was elected president of the Union for 1943–44. The new treasurer is Mr. Clifford Musgrave of the Brighton Museums.

"Geology and Health" was the title of Mr. Bromehead's address. His theme centred around the effect upon the nation's health of minute quantities of certain trace-elements which are only now beginning to be understood or even recognized. In particular he described his own work as a geologist together with medical research into cases of endemic fluorine poisoning. Since 1930, work in the United States and India has shown that as little as one or two parts per million of fluorine in drinking water has a serious effect on human teeth during the period of their formation, and Dr. D. C. Wilson, who has done much work on fluorosis in India, in 1939 found that 'mottled teeth' due to this cause are not uncommon in Great Britain. Water supplies are being examined for its contamination in collaboration with Dr. M. M. Murray, a biochemist. Fluorosis may attack all bony structures in adults as well as children and may produce curvature of the spine, arthritis, neuritis or any rheumatic symptoms and, possibly, goitre. At Hook Norton in Oxfordshire cases of fluorosis have been accompanied by cretinism even where deficiency of iodine is not known; its assimilation may be inhibited by fluorine. Another trace-element of importance is molybdenum, which only affects cattle and sheep—not horses and pigs—through eating the pasture in fields where the soil contains appreciable quantities of that element; the cure is doses of copper sulphate administered to the sickening animals. A plea was made for the closer collaboration of geologists and medical research workers in solving many problems of health in which a geological aspect is involved.

At the sectional sessions the following papers were read: "Manorial Pigeon Houses", by E. Yates; "The Future of Fossil Botany", by Prof. T. M. Harris; "The Future of Quaternary Research in Britain", by K. P. Oakley; "The Recent History of the Rivers near Reading", by Prof. H. L. Hawkins; "A Survey of Malvern in Social Science", by Mrs. D. Farquharson; "Seeds and Seed Growing", by A. P. Balfour; "The Edible Crab", by E. A. Robins; "The Striped Hawk-moth in the British Isles, May-June, 1943", by Capt. T. Dannreuther—the latter on behalf of the Insect Immigration Committee to report greater abundance this year than ever known since the records started in 1824, namely, 340 moths seen and 97 captured and another generation expected in the autumn bred here.

Later, visits were paid to the University of Reading, the Municipal Museum, the Abbey ruins, etc.

T. D.

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Junior Scientific Assistant (male or female) in Agricultural Economics—The Agricultural Officer, University of Bristol, 2 Berkeley Square, Bristol (August 25).

Fieldman (temporary) to the Advisory Entomological Section of the Department of Agriculture—The Registrar, The University Leeds (August 26).

Teacher of Chemistry for Junior work in Technical Day School and Industrial Intermediate B.Sc. class in the Technical College, and a Teacher of Mathematics for Junior work in Technical Day School and Technical and Intermediate B.Sc. Mathematics in the Technical College—The Chief Education Officer, Education Offices, Park Road, West Hartlepool (August 27).

Assistant to the Advisory Chemist (should possess an Honours Degree in Science, with a knowledge of analytical work)—The Advisory Chemist, School of Agriculture, Cambridge (August 28).

Teachers (2) of Engineering Subjects, one of whom should be able to teach some Metallurgy, in the Smethwick Municipal College—The Chief Education Officer, 215 High Street, Smethwick (August 30).

Lecturer in Geology—The Secretary, University of Durham, 38 North Bailey, Durham (August 30).

Lecturer in Mechanical or Production Engineering Subjects up to Higher National Certificate standard in the County Technical College, Wednesbury—The Director (H), County Education Offices, Stafford (August 31).

Lecturers in Mechanical Engineering, qualified to teach Strength of Materials and Metallurgy up to Higher National Certificate standard—The Principal, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17 (August 31).

Psychiatrist (full-time or part-time), and a full-time Educational Psychologist, in the Liverpool Child Guidance Clinic—The Town Clerk and Clerk to the Local Education Authority, Town Hall, Liverpool (endorsed 'Child Guidance Clinic') (August 31).

Professor of Animal Husbandry (Hygiene and Dietetics)—The Secretary, Royal (Dick) Veterinary College, Edinburgh (August 31).

Power Station Superintendent—The Engineer and Manager, Brighton Electricity Undertaking, Electric House, Castle Square, Brighton 1 (endorsed 'Power Station Superintendent') (August 31).

Demonstrator of Biology—The Dean, Guy's Hospital Medical School, Sherwood Park, Tunbridge Wells (September 1).

Lecturer in the Department of Dyeing in the Bradford Technical College—The Director of Education, Town Hall, Bradford (September 1).

Lecturer in Mathematics in the Coventry Technical College—The Director of Education, Education Offices, Coventry (September 7).

Laboratory Steward in the School of Pharmacy—The Registrar, University College, Nottingham.

Scientific Editor of Proceedings, Bulletin, Reports and Publications—The Secretary, British Coal Utilisation Research Association, Experimental Station, Rickett Street, London, S.W.6.

Senior Technical Advisers (3), (Reference No. C.1791), and Junior Technical Advisers (2), (Reference No. C.1792), for general work in the Machine Tool Control Section of the Department of Supply of the Government of India—The Ministry of Labour and National Service, Central (Technical and Scientific) Register (quoting the appropriate Reference No.), Alexandra House, Kingsway, London, W.C.2.

Lecturer (temporary) in the Department of Electrical Engineering—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Deputy Government Chemist for Jamaica—The Ministry of Labour and National Service, Central (Technical and Scientific) Register (Reference No. O.N.F.1525), Alexandra House, Kingsway, London, W.C.2.

Fuel Efficiency Officer (Technical) for the non-ferrous metals (wrought) industry—The Ministry of Labour and National Service, Central (Technical and Scientific) Register (Reference No. O.N.F. 1526X), Alexandra House, Kingsway, London, W.C.2.

Teachers for Evening Classes in Physics up to Intermediate Science standard—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1.

Geography Mistress for a Girls' Boarding College in Natal—Education Committee, Society for the Oversea Settlement of British Women, 3 Sanctuary Buildings, Great Smith Street, London, S.W.1.

PLANS FOR RECONSTRUCTION IN GREAT BRITAIN

THE dangers which follow on the Government's delay in announcing its decisions on the Uthwatt and Scott Reports and in laying down the broad lines of its planning policy become almost daily more apparent. The scope and imaginative courage of the plan for the County of London prepared for the London County Council (see p. 227) is one of the strongest of a number of recent challenges to action. The plan itself is still under discussion by the Council, but obviously it cannot be given proper consideration without reference to other planning authorities. At almost every point regional considerations arise; often they predominate, as, for example, in projects affecting the distribution of industry and of the industrial population.

It is not merely that the size and wealth of the London County Council ensure that its proposals must exert an important influence on the plans of the many smaller authorities. The distribution of open spaces, the layout of roads and railways, the shopping centres, markets and theatres may be largely domestic matters. The grand features of the plan—the dispersal of large numbers of population and the controlled location of industry—are matters of regional and national concern, and their determination involves decisions of national policy. Publication of the plan at the present moment has provided an outstanding example of the way in which the absence of authoritative decisions by the Government creates formidable difficulties in the preparation of reconstruction plans by local planning authorities.

No planning for the location of industry, either in the form of the dispersal of industry and population from congested areas or in the form of the direct provision of industrial employment where it is needed, is possible before the Government has made three fundamental decisions: on the Barlow Commission's proposals for the decentralization of industry; on the Scott Committee's qualifying proposals for the control of construction in rural areas; and on those of the Uthwatt Committee regarding the methods of land control by which the direction of industry and construction are to be effected. The development rights scheme dealing with undeveloped land and the proposals for strengthening public powers of acquisition in urban areas may not indeed be sufficient in the great urban problems such as that of London, as the Uthwatt Report itself indicates. There is, however, no indication of official initiative or of any national economic policy in these vital matters. Without such a national policy adequate schemes cannot be prepared, as the London plan itself demonstrates conclusively. Local planning is at a standstill until the national policy is made known. No lip service to reconstruction will clear the Government of something more than a suspicion of deliberate obstruction if this position persists.

A further difficulty exemplified in the London plan is also emphasized in Guy Hunter's "The British

Way in Local Rule",* and in a recent "Occasional Paper" of the National Institute of Economic and Social Research† by Prof. J. R. Hicks and U. K. Hicks. In the latter paper, which gives a further example of the important contribution which the Institute is continuing to offer to social science and reconstruction, Prof. J. R. Hicks and U. K. Hicks present part of the results of an inquiry into the burden of local taxation which they are conducting on behalf of the Institute. Although this investigation of county boroughs in Britain was limited to an attempt to supply answers to two questions of fact, its conclusions as to policy and as to the functions of local government, together with its observations on the Beveridge Report, give it an importance highly relevant in the present connexion regarding the relations between central and local government in planning.

To the two questions of fact the report returns a straight answer. The main reason for disparity in rates is disparity of wealth. A poor town cannot get enough revenue to reach an average standard demanded by public opinion, backed by direct and indirect pressure of the central government, without imposing a crushing poundage. A rich town can reach the same standard without any strain. As regards the recrudescence of the rate problem, the general growth in the nation's economic prosperity during the nineteen-thirties led very naturally to an increase in local expenditure, which in the fields of health and education left a larger share of the increase to be borne by the rates. The decease of the old Poor Law also placed unforeseen responsibilities on the local authorities, but the revolution in the standards of public assistance was by far the most important factor in the renewed pressure on the rates. To preserve the national resilience against future economic shocks by preventing such possibilities before they occur, the authors suggest that the endemic crisis of public assistance could be ended in a way altogether consistent with present aspirations for social security and also profoundly consistent with the natural evolution of English institutions by a National Board of Guardians to deal with domiciliary relief.

Once again, therefore, we are brought face to face with the need for a declaration of general policy in regard to local government reform, and this in a field closely touching that covered by the Beveridge Report. Moreover, Messrs. Hicks make some pertinent observations on local government generally which accentuate the need for decision. Local government needs to be equitable financially, but it should also be an effective organ of democracy, and this it clearly is not as we have it at present. Again, it is no longer necessary as formerly for such matters as relief to be local responsibilities. Messrs. Hicks point out that we are freer than our ancestors to choose what functions should be allotted to local government, and that we should make our choice, not merely on grounds of efficiency in administration but also with a view to the possibility of using local government to give practice in the working of democracy to far wider circles than can be brought into any intimate contact with the national parliamentary organization.

This goes to the roots of the matter, and no passage in this valuable study deserves to be more widely pondered than that in which the authors indicate criteria on which such a choice could be made. In particular, they refer to the opportunity for achievements of a distinctly local character offered by the field of 'civic amenities' in its broadest sense, including not only highways, housing, parks and public lighting, but also town planning and public buildings. Nor is this all. Analysis of the subject from a point of view totally different from that of Sir William Beveridge has led to the same conclusion as to the urgency of transferring public assistance to central control. This paper, however, directs attention to the dangers which would arise if the Beveridge proposals were enacted and no alteration made in the financial relations between the central government and the local authorities. If the Social Security Plan is not to be, in one important respect, a sham, its cost must be distributed fairly, not only between classes but also between localities. Furthermore, apart from the suggestion, to avoid this danger, of a national rate, emphasis is once more laid on the necessity of a proper regional co-ordination of hospital services. The present extremely haphazard development of such services involves grave danger of disproportionate burdens being placed on the poorer authorities.

The same necessity for finding at the centre the ground plans of policy and the solution of legal and financial obstacles is stressed by Guy Hunter in his pamphlet on the "British Way in Local Rule". For many of the proposed reforms of education, transport and public utility services, as in planning, the areas of operation differ widely from the present local government areas. This administrative difficulty must be faced if we are to draw effectively on the local councils for their experience, leadership and goodwill in the execution of policy. The London plan itself both affords evidence of the value of local tradition and experience and challenges the Government to declare its mind and policy. Paralysis, if not chaos, must speedily result if we are left much longer in doubt as to whether a general reform of local government areas and powers is in prospect, or whether it is proposed to tackle planning first, grafting a new pattern of planning authorities on to the existing structure of local government.

The challenge to Government and Parliament to decide and act on the fundamental assumptions on which the London plan rests is as unmistakable as the challenge which the plan offers to the imagination and resource of London's citizens. Fully as emphatically, however, the recent debate in the House of Commons on the Forestry Commission showed the dangers which have attended the failure to plan with foresight, determination and consistency in the period since the War of 1914–18. The recent report of the

---

† Standards of Local Expenditure: A Problem of the Inequality of Incomes. By J. R. Hicks and U. K. Hicks. (National Institute of Economic and Social Research, Occasional Papers, No. 3.) Pp. 61. (London: Cambridge University Press, 1943.) 4s. 6d. net.

Forestry Commission puts the problem of afforestation, agriculture and rural reconstruction in its right perspective but, as the report itself indicates and as Mr. Clement Davies reminded the House of Commons, n spite of a parallel report twenty-five years ago, mmediately the danger was passed, we reverted to our old chaotic methods.

There can be no question that in this particular matter the Government is right in proceeding with caution, and the assurance of financial continuity in the vigorous execution of whatever policy is finally adopted is all that could reasonably be expected at the moment. Afforestation is essentially a problem demanding a long-term policy of assured continuity. It has to be related to agricultural policy—its relation to hill-grazing requirements was repeatedly stressed in the debate, and Sir William Jowitt intimated that the Government is awaiting reports on the hill sheep ndustry—and a long-term policy for agriculture has yet to be formulated. Again, afforestation, like the larger question of agriculture, is linked with the broad question of export and import policy in our post-war trade, and no continuous long-term policy can be determined without full consideration of these questions also.

The report itself received some criticism as well as praise in the debate and, whatever its intrinsic merits, the scheme proposed is confused in aim and gives no clear guidance as to the real objectives of afforestation policy. There was, however, general support for the view that there should be a more effective central administration of forestry, whether or not it was placed under the Minister of Agriculture, and less reliance on, or tenderness towards, private owners than the report itself suggests. Sir William Jowitt assured the House that forestry would be considered along with post-war commitments as a whole, and that pronouncement on policy would not long be delayed.

With that assurance there would be no reason for dissatisfaction, but for the Government's own record in the field of reconstruction policy. It has to be admitted that some of the matters raised in the Forestry Commission's report, as was noted in the debate, touch on the proposals of the Uthwatt Report in regard to the ownership of land. Others affect the policy of rural reconstruction raised by the Scott Report. Once again we come back to the central point at issue, that over the whole intricate field of post-war reconstruction certain broad and basic decisions of policy are required of the Government before policy can be formulated, nationally or locally, in particular fields, and plans prepared for the execution of such policy regionally, locally, or in specialized fields. Appreciation of the complexity of the situation and the general interlocking of the many post-war problems is widespread and tempers what might otherwise be a dangerous impatience with the Government's delay. If, however, that delay continues indefinitely, impatience may pass into a sense of frustration, with disastrous consequences not only to the war effort but also to our chances of establishing the harmonious co-operation of all the many elements in our institutions—local government, central administration, Parliamentary oversight and technical and professional advice, and above all the keen interest of the average citizen in local rule—on which depend our hopes of building a worthy post-war world.

RECLAIMING THE GREAT WREN

County of London Plan

Prepared for the London County Council by J. H. Forshaw and Prof. Patrick Abercrombie. Pp. xii+188+59 plates. (London: Macmillan and Co., Ltd., 1943.) 12*s*. 6*d*. net.

SELDOM in the history of Great Britain can such a gigantic scheme of land reclamation have been put forward as a practicable proposal; seldom can such a case have been made out for powers to alter the physical environment of a great population. The book of the County of London Plan is first and foremost a quite remarkable essay in public relations, in the right kind of publicity for the special aspect of democratic action which we call 'town and country planning'. Published at a price which must be suited to the purchaser rather than the promoter, beautifully set-out and illustrated, and finely printed, with large coloured maps, descriptive photographs, and a host of diagrams and line drawings, the book is the best ambassador to the public that the plan could have. Neither Moscow nor New York were surveyed so ably and in so popular a format, and only Amsterdam can claim to have produced anything comparable to it. It is not possible to read it without becoming deeply interested in the future of London, as in its past; and in a world of war-time restrictions, this achievement of authors, publishers, printers, illustrators and engravers is, in itself, a matter for congratulation.

With such a complex subject, expert presentation is something to be thankful for; the gist of the matter is nevertheless far from easy to analyse. Clearly the main contribution which the plan makes is its imaginative grouping of the residential neighbourhoods and the commercial and administrative centres, of which London is composed. Its most important proposal is therefore one of density, that is to say, the size of the population and its disposition within the county boundaries, the numbers that are being—or should be encouraged to be—moved out. The elements that must contribute to the realization of such a comparatively stabilized pattern, namely, the roads and railways, the location of workplaces and the provision and maintenance of open space, are all secondary to the social reorganization which is the basis of the plan.

Before examining the road or rail proposals, therefore (which are in fact described as tentative, and for the consideration of a "specially-appointed investigating body"), one must consider the essential principles involved in the proposed re-grouping of the population. These principles are in harmony with enlightened thought in the realms of housing, social science and public administration; nevertheless the consequences of their application in any particular case are liable to be intensely controversial. It may mean flats instead of houses, footways instead of traffic approaches, restriction to a local rather than a central shopping area, or a reduction in the time of journeys to work. Briefly, the plan contemplates "the conservation or creation of communities which would be divided into smaller neighbourhood units of between 6,000 and 10,000 persons, related to the elementary school and the area it serves". Parallel with this the plan proposes three standards of density, reasonable for the central, sub-central, and suburban areas to which they would be applied, namely, 200, 136 and 100 persons to the average acre. These standards are then compared with existing densities, the area in each case being composed of the houses, their gardens and yards, the service and access roads, and half the main roads bounding the site. The excess represents the number to be decentralized from each area; and, allowing for variations in the national population trends, the total for the County of London is estimated to be about half a million.

This establishment of a standard of density, and its use as a measuring rod to determine the degree of congestion, is a difficult business. The authors of the London plan have very courageously proposed these compromise figures, as suitable to the particular case of London, capable of being met without the necessity for perpetrating retrograde housing conditions, and in proportion to their expectations of the corresponding decentralization of industry. Many people will view the compromise as an unhappy one; they will take the view that ideal housing conditions —which means in effect a house and garden for at least 90 per cent of all populations, including that of London—should determine the standard of density, and that industry should be compulsorily decentralized to enable this standard to be carried into effect. Such criticism is logical, but scarcely realistic. As it is, the figures proposed are an enormous advance on present conditions. The number to be housed at a density of 200 per acre (which comes down to less than 100 to the acre when open spaces on the scale of 4 acres per 1,000 of the population are included in the calculation) is only the central 300,000; and most of those are now housed at almost double the density. Mr. Forshaw and Prof. Abercrombie consider that reasonable conditions of access, lighting, open space and so forth, would only be obtained by housing people in flats at this density; but Mr. Trystan Edwards has recently written to *The Times* to state that it could be done with two- or three-floored terrace houses. The intermediate density of 136 would normally require two flats to every house (though again Mr. Edwards states that it could be met by bungalows!); and the lower density of 100 would normally have more houses than flats.

In spite of the formidable opposition already raised against the standards proposed in the London plan, it seems likely that they will find general support; unless really drastic and far-reaching legislation is introduced to bring the ideal nearer to realization.

On the 'community' principle there can scarcely be grave disagreement. Traffic safety, social organization, economy, and neighbourliness, all call for it as an element of town improvement. The amazing biological plate facing p. 21 in the book of the London plan shows the social and functional analysis of the communities of the metropolis. Whether the proposed solution is quite functional enough, or whether an intermediate grouping is desirable between the many reconstructed units and the central areas, will only be proved by time. The main theme is a London reintegrated, and not a London rubbed out and redrawn.

Probably the most unconvincing feature of the plan is that of industrial location. It is unconvincing because even the crowded area of the London County Council is a *local* area, and the industry of London is *national* in character. Certain preliminary facts are sorted out, some of them rather surprising; as for example, that the average number of workers per factory in the County was only 20 in 1938, and tha of 37,000 factories and workshops two-fifths were in the clothing industry. The drift from central to less central areas in search of cheaper land, less congestion and better opportunities for expansion, is clearly faced; and in general the plan proposes that industry, which is anyway on the move, should be encouraged to move to the right places, if not to industrial areas prepared and serviced for its reception. The analysis does not go very far, and much remains to be done in calculating the degree of mobility of the industrial complex, its sex and skil ratios, and the extent to which a system of inducement, coupled or not with licensing powers, would bring about the desired pattern shown tentatively on the coloured plate No. 11. More still depends on the policy which the Government adopts when eventually it faces the issues of the Barlow Report, and the extent to which it is prepared to introduce legislation to regulate post-war industrial settlement But since the standards of density which are at the root of the L.C.C. proposals are based on an estimated rate of industrial decentralization, this is evidently a question of major importance, and one which the plan does not—and probably cannot—answer.

The other proposals are all susceptible to change in detail. The roads are mainly Bressey roads, with additions in the shape of through cross-roads meeting in the heart of London and reaching it partly by tunnel. It is always doubtful whether road improvements may not create as much traffic as they facilitate; and here again everything depends on the extent to which the neighbourhood pattern, imaginative zoning, and the estimates of industrial movement prove adequate to the occasion, and reduce the total amount of unnecessary traffic. The distribution system by an "outer goods ring railway", feeding both in and out by road transport, is a useful suggestion. So is the loop line which joins London Bridge, Cannon Street, Blackfriars, Charing Cross and Waterloo, which it is hoped may eventually be put underground and thus eliminate the cross-river railway bridges. This proposal is similar to that put forward by Westminster in evidence to the Royal Commission on Cross River Traffic in 1926; and since forgotten. But all the railway proposals are tentative, and much will depend on the proposals of the railway companies themselves, if and when these are made public.

For the rest, one can only recommend a study of the many fascinating details which the plan discusses, such as the "precincts" of Westminster and Bloomsbury, the relation of shops to road planning (p. 57), the open space proposals (which would remove once for all the worst features of overcrowding in the most congested areas), the riparian treatment of the Thames, the discussion on "period planning" (p. 145), and the very important Appendix I, giving the figures for decentralization.

However specialists may criticize the plan for failure to clarify particular issues, the fact remains that this proposal puts the whole of the L.C.C. reconstruction scheme into scale and into the proper perspective. It is an enormous and an ambitious challenge to public and to Government alike, to face up to the cost and labour that will be required, and to grasp the inspiring opportunity that is presented to them between the covers of this book.

ARCHÆOLOGICAL FINDS FROM GREECE AND CRETE

The Annual of the British School at Athens
No. 40: Session 1939–40. Pp. iv+87+32 plates. (London: Macmillan and Co., Ltd., 1943.) 42*s.* net.

IN spite of the difficulties of the times, the British School at Athens has produced its fortieth Annual, and the only marks of trouble are the reduced number of pages and a paper cover instead of the usual boards. The number of plates and text-figures is generous, and the contents very well indeed up to the mark.

The article of perhaps the most general interest is Mr. Heurtley's on the School excavations in Ithaca, with his summary of conclusions. Guided by the survival of the name, the general reader has always been content to regard the modern Ithaca, or Thiaki, as the island immortalized in the Odyssey, and if the details of the topography could be shown not to it very exactly in all points, he reassured himself by thinking that Homer was writing an epic poem and not a topographical treatise and, in any event, he had his headquarters somewhere in the eastern part of the Ægean and a very long way from the sland of Odysseus: he aimed, that is, at no more than a general local colour which would pass muster with his hearers. But professional topographers, beginning with Gell, had always felt these difficulties and doubts, and the question came very much to the ore with the activities of Dr. Doerpfeld, who loudly maintained that the real Ithaca of Homer was the sland of Leucas, and claimed that his excavaions there had proved his view. It seems not to have struck him that, as Odysseus was only one of a number of island chieftains, it is hard to see how ny discovery of remains of the required period ould clinch the question. Then the British School began to excavate in Ithaca, and found that it had been inhabited all through the required period, and hus, quite apart from tradition, was no worse off as a candidate for Homeric honours than any other of he neighbouring islands. Finally, the School found a broken mask of the first century A.D. inscribed with the name of Odysseus, to say nothing of potsherds bearing the word *nymphs*. Mr. Heurtley sums up the whole question in his final remark, a model of ommon sense: "To the doubt as to how Odysseus' name came to be associated with Ithaca, the answer is perhaps the simple one, that it was really his home, and it was there that the events took place which supplied the material for Homer's description of the Return."

Of the other articles—there are in all seven—two deal with East Crete. One by Mr. Hutchinson, Miss Eccles and Miss Benton, is devoted to some objects still left unpublished from the excavations at Praisos nd Palaikastro, which began so long ago as 1902. The other is on Dicte and the Temple of Dictæan Zeus; it is a memorandum written before 1910 by the late Prof. R. C. Bosanquet, which seems to have been intended as a historical introduction to the definite report of these excavations at Praisos and Palaikastro, of which this volume contains the aftermath. It is a learned topographical and archæogical study of the whole of East Crete, the Siteia Peninsula, written by one who knew the country well, and it was due to his memory that it should be published. In it are embedded notes of a visit which he paid in 1903 to the island of Kouphonisi off the southern coast of the peninsula, with an account of the remains, Minoan and later, which he found there. Mr. Hutchinson has enriched this study with a note: Where was Dicte?

Other articles are an epigraphical study by J. M. R. Cormack, "Royal Letters in Beroea", a paper by Miss Benton on the dating of early Greek armour, and a long paper by Anton E. Raubitschek, "Early Attic Votive Monuments". This has an interesting note on the sculptor Euenor, the master of Pheidias, and a statue of Athena which might be a work of Euenor, or even (but here the author expresses himself with great caution) of Pheidias himself in his young days.

The last article is by Prof. J. D. Beazley: "An Archaic Greek Statuette from South Arabia". A British officer was riding in the Aden Protectorate and was offered a bronze statuette, five inches high, of a warrior, wearing corslet, helmet and greaves. To buy it was not possible, but a photograph was secured, and an enlargement is here reproduced. The work has every appearance of genuineness, and Prof. Beazley says it would be "good Greek work from the middle of the third quarter of the sixth century B.C.; Peloponnesian and very possibly Laconian". Nothing else of this sort seems to have been found in Arabia, and it well illustrates the never to be forgotten maxim that single finds of almost any sort of object may turn up almost anywhere: certainly few are more astonishing than this one. Apparently the tribesman still has it, unless he has found a passing customer with more ready money in his pocket.

In conclusion: though the volume is slim, the quality is high, and the British School at Athens is to be heartily congratulated on its appearance.

R. M. DAWKINS.

THE FREE WILL CONTROVERSY

The Free Will Controversy
By Dr. M. Davidson. Pp. ix+118. (London: Watts and Co., Ltd., 1942.) 7*s.* 6*d.* net.

A FEW years ago Dr. Davidson published a work entitled "Free Will or Determinism", which was devoted almost entirely to an exposition and discussion of the bearing of modern science on one of the oldest and most perplexing of philosophical problems. Some readers at least felt that the effectiveness of this work suffered somewhat from the lack of a historical setting, and this lack has now been supplied in the volume under review. In a small compass the thoughts of men on the free-will problem have been traced from the early Babylonian astrologers, through Greek, Roman, Hebrew and Christian philosophy, the doctrines of Descartes, Spinoza, Leibniz, Hume, Kant, Mill and Haeckel, to their present preoccupation with the implications of physics and biology. There is a "Conclusion", rightly so called in the sense that it ends the work, but containing no attempt to sum up the evidence or to pronounce a verdict. The treatment throughout is strictly objective and non-partisan, the writing is clear and interesting, and the volume forms a necessary and very useful supplement to the earlier book.

It would be easy but unjust to stress the fact that important omissions have been made. The author is well aware of this, and has, in addition to the obvious defence of its intrinsic inevitability, the further defence that paper restrictions imposed a maximum size on the book. Considering the limits allowed him, it is difficult to see how Dr. Davidson could have made a better choice of material, except that some reference might have been made to the effect on general thought—an effect not completely represented in the standard philosophies of the period—of the mechanistic character of physical science during the eighteenth and nineteenth centuries, for it is only in relation to this that the claims made that modern physics has emancipated us from the chains of "necessity" have any significance. The argument was, briefly, that the movements of matter had been proved to be controlled by universal laws, that human actions were movements of matter, and that therefore human actions were controlled by laws which operated independently of the will of the human being. It was a very weak argument at the best, for the one recognizable distinguishing characteristic of living matter was that it did *not* move according to the laws found valid for non-living matter. Nevertheless, the prospect seemed to cause serious perplexity, and the modern discovery that the laws of motion of non-living matter cannot be effectively used for conceptual entities like electrons unaccountably gave great comfort by making it seem possible that, after all, our bodies after we are dead might not be quite inevitably under the control of physical law. Why this is more consoling than the obvious fact that they are not so controlled while we live would be a suitable theme for Dr. Davidson's next book if psychology is included among his many interests.

H. DINGLE.

THE COMING-OF-AGE OF INDUSTRIAL PSYCHOLOGY

An Introduction to Industrial Psychology

By May Smith, D.Sc. Pp. 264. (London, Toronto, Melbourne and Sydney: Cassell and Co., Ltd., 1943.) 7*s*. 6*d*. net.

PRESENT-DAY psychology can be understood only in its historical setting, which Dr. May Smith outlines in her first chapter, for modern advance in science had strengthened an attitude—even now persistent in some degree—unfavourable to psychological ways of thought. Stahl, "the last of the animists", possessed a knowledge of psychology that had to be rediscovered in our day, and with his defeat the subject was banished from medicine, the branch of science that needs it most. Yet it would not keep out. A century after Stahl there came Mesmer with his theories of magnetic fluids to account for psychological phenomena; another century passed and Charcot, with his *grande hysterie* and metallotherapy, was discredited in his turn. Freud at last provided an understanding of these and other clinical problems, but we were still in the dark age of psychology, and not until the War of 1914–18, with its thousands of breakdowns, was medicine compelled to acknowledge its existence. On the academic side psychology had been a branch of philosophy, but workers like McDougall, with his postulation of instincts as a driving force, were approaching a common groun with Freud; the two lines of descent came togethe and psychology became an integral part of medicine at the same time finding wide application outsid that field.

The author comments, after referring to an earl writer on what we now call vocational guidance "One cannot but regret that this part of his wor did not receive the attention it deserved, but th 17th century had something else to consider, and caught by the exciting drama of the rapid advance in chemistry and mechanics, paid little heed to th suggestions of a writer whose interest was in men' minds".

What was true in the seventeenth century was tru in the nineteenth. Industry had grown up unde economic laws that, though some of their result were softened by legislation, were accepted as no only necessary but also sufficient to ensure th efficiency of the worker. His happiness and contentment were his own private affairs. There was n room for psychology here, but again the War o 1914–18 led to a fundamental change, and under it stimulus was set up the Health of Munition Workers Committee, which gave origin to the Industria Health Research Board and marked the beginnin of great developments in the study of huma problems in industry. In these developments D May Smith, who had been a pupil and fellow-worke of McDougall, has taken an important part, and fe can be better qualified to write a survey of this many sided subject.

Fatigue, the first subject of systematic study, ca be measured by tests and estimated by outpu figures, but, in bringing earlier work into relatio with experience after Dunkirk, Dr. Smith strikes note that prevails throughout the book, and tells u what the workers feel and think. "We shall have t pinch time off if we don't get it" is a sentiment th psychologist would teach us to accept as a factor i absenteeism. Moreover, the ability to listen easil to the expression of such sentiments is essential i the study of problems that appear to be purel physiological—such as lighting, temperature, noise rest pauses, and the like. An account is given, wit references, to work done on these topics, and o accident proneness, training, and vocational guidanc and selection. The chapter on time- and motion study gives full credit to its originator, F. W. Taylor but it is noted that his work was subjected to sever criticism, which arose from his frank acceptance o American economic theory and practice as the existed in 1911, and found its focal point in th phrase 'the number of men required was reduced' Dr. May Smith's thesis is that industrial psycholog gives first consideration to the happiness and well being of the worker, productive efficiency being the natural sequel.

Dr. May Smith's own work led her to the stud of the nervous temperament and its influence upo efficiency and sickness, which she describes with lively human touch. The medical reader will fin here a fuller treatment of the subject than his ow text-books provide, a treatment aided by unobtrusiv psychological knowledge combined with wide experience. The book is an authoritative and up-to date account of the whole subject, and not onl satisfies an urgent need in our present trials but als offers valuable guidance in those new adjustment that will be inevitable when the War shall hav ended.

MILLAIS CULPIN.

EDMOND HALLEY AND GEOMAGNETISM*

By PROF. S. CHAPMAN, F.R.S.
Imperial College of Science and Technology

MY subject is really Halley's geomagnetic work considered in its historical setting, but I wish first to say a little about Halley as poet—a seldom remembered aspect of his remarkable versatility.

Halley's Latin Verses

Halley is known to have written three poems, all in Latin†. The first and major poem, consisting of forty-eight hexameters, was written when he was thirty or thirty-one. It is in praise of Isaac Newton, and was prefixed to the "Principia", which Halley published at his own expense and care. As Prof. H. C. Plummer showed in his Halley Lecture[1] last year, the supreme merit of Newton's work was not immediately and universally recognized. But Halley was in no doubt, and we may imagine his joy and satisfaction in being privileged to evoke Newton's immortal work and to bring it before the world. The hexameters are written in this spirit. In the second edition of the "Principia", edited by Roger Cotes, Bentley amended some of Halley's lines, without leave; in the third edition, edited by Pemberton in 1726, Halley restored most of the original readings[2].

As Latin is now less commonly understood than in Halley's time, I venture to give an English version of this poem made by my wife. This is naturally less concise than the original; the forty-eight Latin lines become sixty-eight in the English.

The poem mentions many of Newton's main discoveries, and describes how Newton has enlarged man's powers and raised him still further above the animals. Finally, it acclaims Newton himself as having done more for mankind than any of its moral and social leaders or the discoverers of the useful arts, placing him of all men next to the Deity.

To the Honour of
this mathematical-physical work
of the most excellent
ISAAC NEWTON
a signal glory of
our Century
and of our human
Race.

Behold, to thee the Rule that guides the Pole,
To thee the balance of the Massive Whole,
To thee the Skies, Jove's holy seat sublime,
Count out their numbered path through Space and Time.
By what Set Laws the All-Father has confined
His own Creative Act thou hast divined,
Hast shewn wherein the Great Creator laid
The Firm Foundation for the world he made.
The Inmost Secrets of the Conquered Sky
Lie open to thy wise discerning eye;
And that same Wisdom all undaunted probes
The Force that spins around the furthest globes.
The Sun commands all things, descending prone
To rush towards him, seated on his throne;
The Starry Chariots suffers not to trace
Straight Paths through the Enormous Void of Space;
Himself the Centre, drawing each, he sways
The Ordered Circuit of their Starry Ways.
Known now the Path the Dreadful Comets weave;
The Bearded Stars no more our minds can grieve.
Wherefore the Silver Moon with varying gait
Speeds on, from thee we learn, though learning late;
Know how she hid, until thy wiser days
The secret of the Curb which She obeys.
We learn from thee wherefore her nodes regress
And why her apses ever forward press.
When Wandering Cynthia doth the sea compel
How Great the Force thy doctrine now can tell,
Measure her Strength, when tired waves leave the shore
And show the sailor sands he guessed before,
Or when, in turn, returning on their way
They seek the utmost marge, beneath her sway.
Those problems which the ancient scholars vexed
Those noisy contests which the Schools perplexed
Plainly we solve—thy lore dispels the cloud
And, by dull error now no head is bowed.
For us thy wit has trod Celestial Ways
And shown the steps of heaven to our gaze.
Mortals, arise! shake off your earthly cares
This Man our Heavenly Origin declares
For fellow minds of such a Master Mind
Are far removed from all the Brutish Kind.
Less did they raise to better things our life,
Our human life, who taught that bloody strife,
That theft, adultery and fraud's wicked guile
Are cursed, and wrote their Lore with graver's stile.
Less he, who to fierce tribes that wandered rude
Taught city life and their wild fears subdued,
Bade them live safe, held in a wall's strong arm.
Less he, who taught the hungry folk to farm.
Less he, who pressed with new devised craft
From the sweet grape her care-dispelling draught.
Less he who, plucking the Nile-watered reed,
Made from it paper, wrote thereon his screed
To painted picture linking spoken sound.
All these for human woes great solace found,
But we of Superhuman Joys are free.
We know the Law that guides the poles, we see
The hidden secret of dark earth unsealed
And Matter's Changeless Ordering revealed.
Such knowledge, hidden from an earlier age,
Is now, through thee, to us an open page.
O Muses, sing with me this Great Man's praise
Ye who are fed with nectar, tune your lays.
Newton, to Truth's locked Shrine has found the Key,
Newton whose heart is pure, in whom we see
The Godhead's Favoured Friend to whom is given
The Nearest Place a man may win to Heaven.

Halley may have written another poem[3], now lost, in the year 1687 when the "Principia" was published. His two other known poems appeared thirteen years later, on his famous world magnetic chart; this, too, must have been for him a time of great joy in achievement. One poem was in praise of Queen Anne, and is now of little interest; the other, as follows, of much greater artistic merit, lauded the unknown inventor of the compass[4].

Him who first taught with magnetism to imbue
The iron: and the ocean's watery waves
Made clear to ships erst doubting: him who linked
Shores, tell his time far sundered, and by wind
Brought mutual products to remotest lands.

---

* Halley Lecture delivered at Oxford on May 28.

† Halley also used Latin in his first paper in the *Philosophical Transactions of the Royal Society*, in his Catalogue of the Southern Stars, and occasionally in later papers. Hevelius, in a letter of July 5, 1670, to the Royal Society, published in the *Phil. Trans.* for that year pp. 2059–2061), opens with the sentence: "Would to God, that hose Excellent Books that are publish'd in English, were, for the benefit of the whole Learned World, made Latin."

A thankless day, a heedless age have hid.
No mighty name survives him, being dead.
Hope not to wrest thy fame from Stygean shades
Nor seek to win thy ashes honours due.
And yet—to know within thy secret heart,
A shell surpassing common mortals, to have blessed
The life of far-off grandsons, is not this
Itself the Elysian fields, the shining crown ?

The Magnet and the Compass

The science of geomagnetism has a long history. In our time its earlier phases have been studied especially by Crichton Mitchell[5], and in the preceding generation by Hellmann[6] and Sylvanus Thompson[7].

The attraction of iron by the magnet or loadstone was known to antiquity, and is mentioned by Plato and many later writers[7]. The directive property of the magnet was discovered much later ; Crichton Mitchell[5a], after reviewing the available evidence, concludes that it was certainly known to the Chinese in the eleventh century, and in Europe in the twelfth. A Chinaman, Shon-Kua (A.D. 1030–93), wrote that "fortune-tellers rub the point of a needle with the stone of a magnet in order to make it point south". Before 1200 Alexander Neckam, a monk of St. Albans, described the mariner's compass, in which a magnetic needle swings on a pivot, as being in common use.

The compass points south, said the Chinaman, north, said the Europeans ; both were right. Though the choice is arbitrary, it affected men's ideas as to the cause. In Europe the Pole Star was often supposed to attract the north end of the needle.

Nowadays a boy's first lesson on magnetism describes the dipolarity of magnets, the north and south poles (named by means of the directive property), the repulsion of like poles and the attraction of unlike. Petrus Peregrinus in 1269 gave the first-known systematic record of these facts, in a letter[8] from Italy to a home friend in Picardy. Manuscript copies spread the knowledge ; the letter was not printed until 1558. Though it includes a description of an ingenious magnetic perpetual motion machine, the letter is generally clear and modern in spirit ; Petrus wrote from actual experiment, mostly using loadstones cut to the spherical form.

Magnetic Declination

The recognition of the magnetic declination* as a general fact of Nature came only gradually. The declination of the compass from the true north cannot be measured without first determining the meridian at the place of observation, and this requires skill. At first the declination was ascribed to faults in the magnetic needle or in the measurement. Even in 1701 two needles used by Halley on his magnetic voyages gave readings of the declination at London that differed by 20′ ; in the fifteenth and sixteenth centuries the errors in magnetic azimuths might be a few degrees. Nowadays at magnetic observatories the declination is read[9] to 0·1′, though this requires great skill and care.

Our earliest dated records of the magnetic declination are not written ones. In the fifteenth century, portable sun-dials[10] were used by travellers and others to tell the time ; they included a magnetic compass by which to set the noon line. Some dial maker who had determined his true meridian must have noticed that the magnetic setting was erroneous, so he put a mark on his dials to which the needle should point. The angle between this mark and the north point of the dial showed the declination, as reckoned by the maker. Dated dials made at Nuremberg at about 1450 show that the declination there was then about 7° E.

A little later, before 1500, road maps made by Etzlaub of Nuremberg[11] bear instructions for their use in association with the traveller's compass, and show clearly that the declination was known. A compass card printed on one such map has an arrow pointing 11¼° E. (one-eighth of a quadrant, the smallest unit then commonly used in stating wind directions).

Crichton Mitchell[12] has carefully examined the statements often made that Columbus, on his West Indian voyage in 1492, discovered the declination or the fact that it is not everywhere the same (ref. 6*a*). He concludes adversely on both points, stating that Columbus misinterpreted the differences observed between his compass readings ; he also rejects similar claims made on behalf of the Cabots.

Measuring the Declination

The first printed instructions for measuring the declination were given in the earliest printed treatise on navigation, by a Portuguese writer Falero[13], in 1535. They were mainly astronomical, to determine the true meridian. Magellan seems to have taken a manuscript copy of this book with him in 1519 on his voyage round the world. The first notable series of forty-three observations of the declination were made by the great Spanish navigator de Castro, in a voyage to the East Indies and the Red Sea, 1538–1541. The custom spread to later navigators, and knowledge of the declination in various seas slowly grew.

But this knowledge was very imperfectly diffused, and many landsmen and seamen in other countries remained ignorant of the methods used and the observations made by the navigators of Spain and Portugal. Most writers on magnetism and dials up to 1600 fail to refer even to the existence of the declination[14].

The earliest known written record of the declination gives it for Rome, 6° E., in 1510. It occurs in a letter[15] sent by Georg Hartmann in 1544 to Duke Albrecht of Prussia ; the measurement was made while Hartmann, a mathematician, instrument maker, and later vicar of a Nuremberg church, was studying in Rome. In Nuremberg, when he wrote, he found the declination to be 9° or 10° E.

This letter contains also the first mention of the magnetic dip. It describes how a needle perfectly balanced before it was magnetized dipped about 9° after being stroked by the loadstone. Hartmann contented himself with this private mention of his observation, which he regarded as one more wonder and mystery of the magnet ; the dip must really have been much more than 9°. The letter remained unknown in the Königsberg archives until 1831.

In 1581 Robert Norman, a London seaman and instrument maker, published "The Newe Attractive", a small book said by Hellmann to be the first printed work purely on geomagnetism. It announced the discovery[16], probably in 1576, of the magnetic dip, which Norman gives as 71° 50′.

The book also describes new experiments of great interest. Norman showed that, when care is taken, a floating compass is not drawn bodily northward, but only turns on its centre ; hence, said he, earlier writers erred in discussing where lies the *poin*

---

* Or magnetic *variation*, as it is called by seamen and many old writers on geomagnetism.

attractive of the compass; the compass is not attracted to any point, but there is a point which it respects and turns to; so he discarded the old term *point attractive* for his new term *point respective*.

In making this important distinction he did not discriminate between the whole compass and its northern end, to which he, like earlier non-Chinese writers, gave a preference. As the northern end dipped, he located the point respective in the earth.

Important ideas were struggling to birth in the mind of this practical seaman and mechanic, more discerning than Hartmann. He was right in concluding that the earth, not the heavens, directed the magnetic needle; but his argument was faulty in that it depended on an unconscious preference for the north end of the needle. The idea of a couple acting on the needle still lay far in the future, beyond even Halley a century later.

William Gilbert, Queen Elizabeth's physician, laid a firmer foundation for Norman's conclusion. In the great treatise "De Magnete" (1600), Gilbert announced that the earth itself is a great magnet. This book, written in Latin, describes a great variety of his own experiments, and clearly distinguishes between magnetic and electric attractions. Gilbert chiefly used spherical loadstones, like Petrus Peregrinus three and a half centuries before; he carefully explored how tiny magnetic needles, free to turn on their centres, set themselves when placed at different points near such a stone or terrella. He found that at the 'equator' of the stone, midway between its pôles, the needle would lie along the surface, whereas nearer the poles one or other end would dip; by means of the needles, he marked out on his terrella, with chalk, the magnetic meridians or lines of horizontal magnetic force, converging to the two poles.

He pointed to the analogy between the poleward direction of these little needles on the sphere, and the northward direction of compass needles on the earth. He fortified the analogy by Norman's observation of the magnetic dip*, roughly equal to the dip of his own little needle on the sphere, when placed in a similar 'latitude'. As the magnetism of the terrella obviously controlled the direction of his needles, he inferred, as Norman had done, but now with more reason, that the earth controls the direction of the compass or dip needle. Going beyond Norman, he realized that the earth itself is a great magnet.

Thus he showed that the directive property of the magnet, which hitherto had been regarded as a phenomenon distinct from its attractive or repulsive action, was really only a manifestation of the same power, in relation to the earth magnet, the bigness of which had until then hindered this recognition.

Gilbert commended Norman's rejection of the old idea of a *point attractive*, but himself rejected Norman's *point respective*, because the little needles, placed at different points on the terrella, met in no common point. The whole earth, he said, exerts the directive power, not merely the centre or any other single point.

Distribution of the Declination

Falero, in the treatise already mentioned, stated without any warrant from observation that the magnetic declination was distributed regularly over the earth. At that time the declination was zero at one of the Azores. Falero said that, going eastward from this meridian, the declination would be east, and would regularly increase over the first 90° of longitude; thence it would regularly decrease to zero in the next 90° of longitude; in the 180° of west longitude the declination would be westerly and would vary in the same way.

Gilbert knew that its distribution was less regular than this. He quoted (Bk. IV, Ch. 1) the declination at London and elsewhere, and concluded that the earth's directive power was defective over the oceans (water being non-magnetic) and stronger where the land was elevated. He regarded these inequalities as disturbing the tendency of the needle towards the magnetic poles, which he supposed to coincide with the geographical poles. Halley afterwards disproved Gilbert's theory, showing that at sea the needle may point away from an adjacent continent.

Gilbert and the Magnetic Dip[17]

Gilbert also erred like Falero in thinking that the earth's magnetism is more regular than is the fact; but Gilbert's error concerned not the declination but the dip. He supposed that the dip depends only on the latitude, and would enable seamen to determine their latitude when clouds covered the sky. He gave an empirical theory for the magnitude of the dip, and Briggs of Gresham College, at Gilbert's suggestion, calculated a table of dip and latitude on this theory. Kircher, a Jesuit writer on magnetism, in 1643 gave a table[18] of computed and observed dips. Further discovery showed that the method was impracticable.

It is remarkable, in view of the importance of the dip in Gilbert's demonstration that the earth is a great magnet, that he quoted not one actual observation of it, neither Norman's nor any made by himself, though he invented a simplified portable dip circle[19].

Gilbert made the further unfounded assertion that at any one place the declination remains constant, unless changed by some great cataclysm like the fabled submergence of Atlantis. This was disproved in 1634 by Gellibrand[20], Gresham professor, who found that the declination at London was then only 4·1° E., quite irreconcilable with the value 11·3° E. measured in 1580 by William Borough[21].

Thus the secular magnetic variation came to light, which imposes on us the duty, both for science and practice, continually to repeat the magnetic survey of the globe. The earth's magnetism has changed greatly in the three centuries since then, and its future, uncertain and mysterious, remains to be observed by later ages.

Halley and his Magnetic Needle

The story of magnetic discovery has now brought us to the time of Halley[22,23], who was born in 1656[24]. While still at St. Paul's School, he decided to devote his life to astronomy, which he did to such effect that his name will ever live in the annals of that science. But geomagnetism was one of his favourite secondary interests. In 1672, while only sixteen and at school, he measured the magnetic declination in London; it was 2° 30′ W., showing a further westward change of $6\frac{1}{2}°$ since Gellibrand's observation. The laying down of the meridian for this measurement fitted in well with Halley's astronomical interests.

At Oxford, Halley planned an expedition across the equator to observe the southern stars, and in 1676 he was enabled to go to St. Helena, through the good offices of the Royal Society, King Charles II.

---

* Gilbert called the declination the *variation*, and the dip the *declination*.

and the East India Company. There he spent a year (1676–77) most fruitful for astronomy. He took his magnetic needle with him, besides his astronomical equipment, and observed the declination[25,26] at St. Helena and Ascension.

Not long after his return to England and the publication of his results, he paid an astronomical visit to Hevelius* at Danzig, where again he appears to have used his compass[25]. A little later he set out from England to make the grand tour with a friend; while in Paris and Rome he observed the declination[26]. In London, at Gresham College, then the home of the Royal Society, he often repeated his measurement[27], for example in 1683, 1692, 1701, 1702, and 1716. In 1696, when he went to Chester as deputy controller of the Chester Mint, he again took his magnetic needle with him[28]. These observations clearly show his long-continued interest in the earth's magnetism.

Halley's Theory of the Variation (Declination)

In 1682 Halley married and settled down in London. The next year, when he was twenty-seven years of age, the Royal Society published his famous theory of the distribution of the declination[25]. His aim was "to reconcile the observations by some general rule", not, as Des Cartes[29] did, by "causes altogether uncertain (as are the casual lying of iron mines and loadstones in the earth)", which to Halley seemed to "put a stop to all further contemplation, and give discouragement to those that would otherwise undertake this enquiry".

"Tis true," he said, "that not long since one Mr. *Bond*[30], an old teacher of navigation, put forth a small treatise wherein he pretends to calculate the variation." Bond's theory merely supposed the magnetic axis of the earth to be oblique to the geographical axis, so that the declination could be readily calculated anywhere. Halley saw that this theory requires the declination to have the same sign all along each geographical meridian, and showed that this did not agree with observation[31].

Halley then gave a table of dated observations of the declination, made by "persons of good skill and integrity", at forty-eight places in many parts of the globe. He showed that these did not confirm Gilbert's theory that at sea the compass would always turn to an adjacent mainland. As to Des Cartes, Halley admitted that some local irregularities of the declination, like those near Elba, might be explained by local deposits of iron ore; but he said that no reasonable amount of it could explain why the needle declines the same way all over great areas such as the whole Indian Sea. "Besides, against both Des Cartes and Gilbert, the change of the variation, which has been within this hundred years last past more than 15 gr. at London, is an entire demonstration: tho Des Cartes does not stick to say, that the transportation of iron from place to place, and the growth of new iron within the earth, where there was none before, may be the cause thereof."

Halley himself, "after a great many close thoughts", and wishing to "introduce nothing strange in philosophy", could "come to no other conclusion than that, *The whole globe of the earth is one great magnet, having four magnetical poles, or points of attraction, near each pole of the equator two, and that, in those parts of the world which lye near adjacent to any one of these magnetical poles, the needle is governed thereby, the nearest pole being always predominant over the more remote*".

Halley gave the positions of the four poles, "as near as conjecture can reach", "for want of sufficient data to proceed geometrically"; and he indicated the four regions, each governed mainly by one of these poles. He ended with the following admirably moderate remarks[32] on the declination:

"But to calculate exactly what it is, in any place assigned, is what I dare not yet pretend to; . . ., for first there are a great many observations requisite. . . . And besides it remains undetermined in what proportion the attractive power decreases, as you remove from the poles of a magnet; without which it were a vain attempt to go about to calculate. There is yet a further difficultie, which is the change of the variation, one of the discoveries of this last century: which shows, that it will require some hundreds of years to establish a compleat doctrine of the magnetical system . . . it should seem, that all the magnetical poles had a motion westward: but if it be so, tis evident that it is not a rotation about the axis of the earth . . . But whether these magnetical poles move altogether with one motion, or with several, . . . are secrets as yet utterly unknown to mankind; and are reserved for the industry of future ages."

Halley's Experiments on the Law of Magnetic Attraction

In 1687 Halley made experiments[33] to determine "in what proportion the attractive power decreases, as you remove from the pole of a magnet"; this was one of the needs that hindered the completion of his theory. But his work was inconclusive; the discovery of the inverse square law of force between point magnetic poles did not come until a century later. In Halley's time several necessary theoretical conceptions were wanting—the point pole, the point dipole, the magnetic moment, the couple. Newton might have developed these had he given his close attention to magnetism; but Halley, who did so much in connexion with Newton's "Principia"*, seems never to have inspired Newton with his own strong interest in magnetism.

Halley's Theory of the Secular Magnetic Variation

In 1692 Halley, aged thirty-six, extended his theory to explain the secular magnetic variation[26]. He said that his theory of the declination had been well received at home and abroad, but he found two difficulties not easy to surmount. One was that no magnet he had ever seen or heard of had more than two poles, "whereas the earth had visibly four, and perhaps more". The second was that "these poles were not, at least all of them, fixt in the earth, but shifted from place to place"; "whereas it is not known that the poles of a loadstone ever shifted their places in the stone, nor (considering the compact hardness of that substance) can it easily be supposed.

---

* Hevelius also was interested in the magnetic declination, and in a letter to the Royal Society (*Phil. Trans.*, 5, 2059–2061; 1670) mentions his own observations of the declination at Danzig in 1628, 1642 and 1670.

* Newton's "Principia" contains only five brief references to magnetism; in Axioms, Corollary 6; Book 2, Section 5, Theorem 18; Book 3, Theorem 6, Corollary 5; Theorem 7, Corollary 1; Problem 18, Corollary 10. The third of these references includes the sentence: "The power of magnetism . . . in receding from the magnet decreases not as the square but almost as the cube of the distance, as nearly as I could judge from some crude observations". Newton in 1712 (see ref. 23) made the same remark, when proposing, as president of the Royal Society, that Halley and Hawksbee should make new experiments on the subject.

"These difficulties had wholly made me despond, and I had long since given over an enquiry I had so little hopes of; when in accidental discourse, and least expecting it, I stumbled on the following hypothesis:

"Now considering the structure of our terraqueous globe, it cannot be well supposed that a very great part thereof can move within it, without notably changing its centre of gravity and the equilibre of its parts, which would produce very wonderful effects in changing the axis of diurnal rotation, and occasion strange alteration in the sea's surface, by inundations and recesses thereof, such as history never yet mentioned . . . So that the only way to render this motion intelligible and possible, is, to suppose it to turn about the centre of the globe, having its centre of gravity fixt and immoveable in the same common centre of the earth: and there is yet required that this moving internal substance be loose and detached from the external parts of the earth, whereon we live; for otherwise were it affix'd thereto, the whole must necessarily move together.

"So then the external parts of the globe may well be reckoned as the shell, and the internal as a nucleus or inner globe included within ours, with a fluid medium between. Which having the same common centre and axis of diurnal rotation, may turn about with our earth each 24 hours; only this outer sphere having its turbinating motion some small matter either swifter or slower than the internal ball."

Both the exterior shell and the nucleus were supposed to have their poles distant, by different amounts, from their poles of rotation. The exterior shell, with its magnetic poles fixed, might also have an unequal or irregular distribution of its magnetic matter, explaining the local irregularities in the distribution of the declination. The relative motion of the magnetic nucleus, or, should future observations require it, of the nucleus and additional inner shells, may explain the secular variation, though "it will be very hard to bring this hypothesis to a calculus".

Halley conjectured that the whole period of the secular variation is "700 years, or thereabouts; so that the nice determination of this and of several other particulars in the magnetick system is reserved for remote posterity; all that we can hope to do is to leave behind us observations that may be confided in, and to propose hypotheses which after ages may examine, amend or refute. Only here I must take leave to recommend to all masters of ships and all others, lovers of natural truths, that they use their utmost diligence to make, or procure to be made, observations of these variations in all parts of the world, . . . , and that they please to communicate them to the Royal Society, . . ."

Halley then answers various objections which he foresaw: one was that there is no instance in Nature of the like thing, and that if there were, the nuclei and shells would not preserve the same centre. To this he answers that the ring of Saturn is a notable instance somewhat of this kind. Another objection was that water would leak through the outer shell.

"To those that shall enquire of what use these included globes can be, it must be allowed that they can be of very little service to the inhabitants of this outward globe; nor can the sun be serviceable to them, either with his light or heat. But since it is now taken for granted that the earth is one of the planets, and they all are with reason supposed habitable, though we are not able to define by what sort of animals; and since we see all the parts of the creation abound with animate beings, . . . , all whose ways of living would be to us incredible did not daily experience teach us. Why then should we think it strange that the prodigious mass of matter, whereof this globe does consist, should be capable of some other improvement than barely to serve to support its surface? Why may we not rather suppose that the exceeding small quantity of solid matter in respect of the fluid ether, is so disposed by the Almighty Wisdom as to yield as great a surface for the use of living creatures as can consist with the conveniency and security of the whole. We ourselves, in cities where we are pressed for room, commonly build many stories one over the other, and thereby accommodate a much greater multitude of inhabitants."

Lastly, he explains a diagram showing a nucleus and three shells, the nucleus being about 2,000 miles in diameter, and the thickness of each shell, and of each hollow between, about 500 miles, so that the four upper surfaces are "nearly proportionable to the magnitudes of the planets" Mercury, Mars, Venus and, of course, the earth.

"Thus I have shewed a possibility of a much more ample creation, than has hitherto been imagined; and if this seems strange to those that are unacquainted with the magnetical system, it is hoped that all such will endeavour first to inform themselves of the matter of fact, and then try if they can find out a more simple hypothesis, at least a less absurd, even in their own opinions. And whereas I have adventured to make these subterraneous orbs capable of being inhabited, 'twas done designedly for the sake of those who will be apt to ask *cui bono* and with whom arguments drawn from *final causes* prevail much."

Comments on Halley's Magnetic Theories

How are we to regard this remarkable theory? To us, and probably to some of his contemporary critics, it has some flavour of Kepler in his wilder moments. Halley himself said: "If I shall seem to advance any thing extravagant or romantick, the reader is desired to suspend his censure, till he have considered the force and number of the many arguments which concurr to make good so new and so bold a supposition". A sign that Halley always remained satisfied with these arguments is that a portrait painted in 1736, when he was eighty, shows him holding his 1692 diagram of the earth's nucleus and its shells.

The force and ingenuity of his arguments cannot be gainsaid, and they must be judged by the standards of knowledge and ignorance at the time they were written. But our knowledge of geophysics, especially of seismology, now precludes Halley's hypothesis.

What is more pertinent, however, is that Halley might have found for himself, by experiments like those of Petrus Peregrinus and Gilbert, using loadstones in the form of a sphere and spherical shells, that his hypothesis would not work. The theory of uniformly magnetized spherical shells still lay far in the future, but this experiment was quite open to Halley, and would have shown him that despite the differing directions of the magnetic axes of the nucleus and shells, the field at the outer surface would have only two poles.

We know now that despite the irregular distribution of the earth's field, there are only two magnetic poles*, to which converge all the magnetic meridians (drawn as Gilbert did on his terrella). Halley's own later knowledge would have enabled him to draw many of these meridians, and to discover this fact. The first actual chart of the earth's magnetic meridians was made in 1817 by another Englishman, Thomas Yeates[34].

The irregularities of the earth's field imply a more detailed irregularity in the inner causes than Halley's hypothesis suggested, and the secular variations are regional in character, not so regular and world-wide as he supposed.

The causes of the main field, of its irregularities, and of its secular variation, are still unknown. It seems likely that the secular variation is connected with convective motions inside the earth, the substance of which becomes first plastic, and then liquid, with increasing depth.

Halley's Magnetic Voyages and Charts

Halley's magnetic theories extended and maintained interest in magnetic observation. Already in 1692 Halley was associated[35] with a plea by Benjamin Middleton, a fellow of the Royal Society, for the Society's assistance "to procure for him a small vessell of about 60 tuns to be fitted out by the Government, but to be victualled and manned at his own proper charges. And this in order to compass the globe, to make observations on the magneticall needle, &c. The President in the name of the Society promised to use his endeavours towards the obtaining such a vessell".

This plan came to nothing, but in 1698 Halley was granted a vessel, the *Paramour* pink, by King William III, "to improve the knowledge of the longitude and the variations of the compasse". Moreover, this landsman of forty-two was put in command of the vessel, with a captain's commission in the Royal Navy—a remarkable event which his deeds well justified. He sailed in November 1698, but trouble with an insubordinate lieutenant caused him to return from the West Indies the following summer, without having crossed the equator. He set off again in September 1699, and after a magnetic survey of the North and South Atlantic down to a high southern latitude he returned in August 1700[36]. In 1701 he published his first chart of the declination over the Atlantic Ocean. In 1702, having collected further observations by mariners in other oceans, he produced a world magnetic chart[37].

These famous charts are Halley's greatest contribution to geomagnetism; they give the declination in a way[38] very convenient to the navigators for whom they were made, and by whom they were widely used for forty years. In time, as Halley foretold, their practical value came to an end, owing to the secular magnetic variation, and new charts replaced them. But the value of Halley's observations as a record of the declination at the epoch 1700 remains imperishable.

One may lament, however, an astonishing gap in Halley's geomagnetic work, his apparent total neglect of the magnetic dip—a fact most surprising in view of his great geometrical knowledge and insight, and of the importance given by Gilbert to the dip in his demonstration that the earth is a great magnet. The dip circle is a more difficult and less accurate instrument than the compass, but its reference direction, the horizontal, is much more easily obtained than the meridian needed in observing the declination. Had Halley observed the dip as well as the declination our debt to him would have been doubled; but where so much is owed, gratitude and admiration must far outweigh these vain regrets.

Halley's Later Geomagnetic Work

At least as late as 1721, Halley's published papers manifest his continued interest in geomagnetism. He became the channel by which many observers sent their magnetic measurements to the Royal Society. He likewise presented and discussed many series of observations of two great auroras visible in London, in March 1716 and November 1719. He acutely recognized some of the relations between the auroras and the geomagnetic field, both as regards the location of auroras in high magnetic latitudes and the parallelism of their rays with the magnetic dip needle.

Halley seems to have contemplated further magnetic voyages, because in 1705 Leibniz[39], replying to an astronomical inquiry from Halley, who had then become Savilian professor of geometry at Oxford, genially expressed the hope that younger men would be found to take over the further little excursions of a few thousand leagues which Halley had been considering, to complete his solution of the great magnetic enigma.

But for two centuries Halley had no comparable successor in this field, and the magnetic survey of the globe was not renewed with his abounding zeal until in 1905 the young American, Louis Bauer, with the backing of a prince of industry, the one-time poor Scots lad Andrew Carnegie, resumed the Sisyphean task.

A non-magnetic ship was built for the ocean magnetic survey: unfortunately this was lost by fire in 1929. Later the British Admiralty built another non-magnetic ship, the *Research*, which should by now have completed its first voyage had war not intervened. We may hope that when peace returns the great work which Halley so well began will be taken up again with his own vigour.

MORE AND BETTER MILK

IT is common knowledge that while the average diet in most European countries has been seriously worsened by the War (in certain countries it is reported to have been deliberately reduced by the Nazis well below the minimum subsistence-level), the present diet in Great Britain, though drab and much restricted as to choice of food, is still from the point of view of the nutritional scientist little, if at all, inferior to pre-war standards. In fact, as a result of the rationing system and the more even distribution of purchasing power, it is probably true that the great majority of our population is better (or perhaps one ought to say less badly) fed than before the War.

That this is so is due in no small part to the facts that it has been possible (*a*) to maintain the *total* home production of milk at its pre-war level; (*b*) to increase considerably the quantity of *liquid* milk consumed (at the expense of milk which was, in pre-war days, manufactured into products valuable and delectable in themselves but the preparation of which entailed very considerable losses of nutritive value in the shape of whey and skimmed milk, little of which was consumed by the human population); and (*c*) to increase slightly the amount of liquid milk produced in winter when milk is more difficult and economically more costly to produce than in summer. As regards (*b*), during the last three years the yearly liquid milk intake in Britain has risen until it is now about 40 per cent above pre-war level. This is a continuation of a tendency that was clearly evident before the outbreak of war. In 1938, for example, the liquid milk consumption per head in England and Wales rose by 11 per cent.

For the first time in our history a comprehensive Government milk policy, in which the Ministries of Food, Health and Agriculture are collaborating, is now in action, based on the key nutritional importance of milk in the war-time dietary. A number of different but associated schemes have been introduced to implement that policy. They include on the consumption side an extension of the pre-war milk-in-schools scheme, the legislation for giving priority of liquid milk supplies at reduced cost to expectant and nursing mothers and children less than five years of age and to certain classes of invalids, and on the production side the priority given to dairy cows in the animal feeding stuffs rationing scheme, the nation-wide drive through the County War Agricultural Executive Committees to stimulate milk production, the voluntary 'panel' scheme arranged a few months ago between the Ministry of Agriculture, the National Farmers' Union and the National Veterinary Medical Association for the control of certain diseases affecting dairy cows, the national milk testing and advisory scheme to prevent milk souring and to disseminate knowledge of methods of clean milk production on the farm and of hygienic milk handling off the farm, together with national schemes for milk recording and live-stock improvement.

A joint meeting of the Nutrition Society and the Food Group of the Society of Chemical Industry took place at the London School of Hygiene on July 3 to review the nutritional aspects of these and other recent developments and trends in milk policy. The chairman (Prof. H. D. Kay), in his introductory remarks, pointed out that the future of national nutrition is bound up to a great extent with milk production, and that the future of milk production is in a very real way the future of British farming. He emphasized the present difficulties under which milk producers were working, and pointed out the urgent need for improved technical training both for the future dairy farmers and for those entering the technical and scientific side of the milk processing and distribution industry. For the latter entrants there was at present, as before the War, scarcely any advanced vocational training in Great Britain.

The first paper was given by Mr. J. L. Davies, on the production, supply and marketing of milk. He emphasized the enormous size of the milk industry, with a capital estimated (in pre-war values) at £350–£400 millions, and with between 400,000 and 500,000 people actually engaged in milk production, processing and distribution, apart from those in the ancillary industries of feeding stuffs, manufacture and production of dairy machinery, equipment, etc. Of the herds owned by our 150,000 dairy farmers, 36 per cent contained less than 10 cows, 45 per cent 10–25 cows, 15 per cent contained 25–50 cows and only 4 per cent contained more than 50 cows. While the average yield of milk per cow had gone down since the War, he considered that the pre-war average milk yield for the cow in the older established dairying herds was considerably greater than the average for the whole country (which included some herds mainly kept for breeding and rearing purposes), say, 600–650 as against the total country average of 500–550 gallons. There was room for improvement in yield and in methods of milk production, and steps were now being made through W.A.E.C.s to achieve as much as was possible in war-time. Mr. Davies suggested a ten-year plan, to rebuild and re-equip our dairy farms, to bring water supplies and electricity to them, and to render them relatively disease-free. He advocated a six-day (and not, as at present, a seven-day) week on the dairy farm. His ten-year plan would include the steady raising of milk consumption to at least 0·75 pint per head per day accompanied, of course, by the same increase in milk production, which he was sure the industry could provide during the same period. He considered we should plan now.

In the discussion on this paper, Dr. Wooldridge emphasized the importance of disease control on the farm. Disease placed a high and unnecessary tax on the economic cost of milk production. Prof. A. W. Ashby, while supporting the need for greater efficiency in the industry, which could only be achieved by national planning, considered that the economic effect of disease was exaggerated. Dr. Stableforth held the opposite view. Mr. Davies' paper and the discussion which followed took up the whole of the morning session.

In the afternoon, Dr. A. T. R. Mattick dealt with the bacteriological aspects of milk processing. Pasteurization, if properly carried out, both greatly increased the keeping quality of milk and destroyed all the common pathogenic organisms that might occur in raw milk. The difficulty was to ensure that pasteurization *was* properly carried out. For public health reasons there should be filtration of the milk *before* pasteurization. The provisional regulations for the new attractive alternative of high-temperature short-time pasteurization (not less than 162° F. for not less than fifteen seconds) allowed a margin of safety, but the thermometric apparatus controlling flow diversion valves lacked, in some machines, speed of response to changes in temperature. He discussed recent findings on the occurrence in milk of pathogenic and other organisms. Aseptically drawn milk from healthy animals contained only micrococci and Corynebacterium sp., organisms which did not survive ordinary pasteurization. In fact the organisms in cleanly but not aseptically drawn milk were all vulnerable to pasteurization. This was not the case with raw milk reaching the average pasteurization plant, in which heat-resistant organisms were of frequent occurrence. The bacterial quality of raw milk seriously affected the bacterial quality of the milk after pasteurization. Dr. Mattick very much doubted the value of the plate count as a measure of efficient pasteurization. He considered that there was much room for improvement in the design of bottle-filling and bottle-washing machines. With improved methods of production and control on the farm, coupled with improvements in processing technique and particularly in the manipulation of milk after heat treatment, "we have the possibility of furnishing the people with a product of such superb quality as is at present visualized only by the few".

Dr. S. K. Kon followed with a paper on the chemical composition and nutritive value of milk and milk products. This paper gave a wealth of recent quantitative findings impossible to summarize in a review. Milk varied in chemical composition and nutritive value not only with the breed and health of the cow, but in the same healthy cow from one season of the year to another. The diet of the cow was largely responsible for changes in the vitamin A content of milk and to a lesser extent for the changes in riboflavin; but vitamin B_1, which was synthesized in the bovine rumen, was fairly constant in quantity throughout the year. Vitamin C was synthesized by the cow, but unlike the B vitamins the synthesis did not take place in the rumen. It was unfortunate that milk was lowest in vitamin content in early spring, since most other human foodstuffs were at that season at their nadir of nutritional value. He considered that more attention should be paid in future to nutritive quality of milk produced in Great Britain.

The effect on the nutritive value of milk of pasteurization, sterilization, drying and condensing was stated in some detail by Dr. Kon. Commercial pasteurization brought about a loss of vitamin C of the order of 20 per cent, caused rather by exposure of the milk to light than to heat, and a still smaller percentage loss of vitamin B_1 but no other change of nutritional significance. The effect of sterilization was rather larger—a loss of half the vitamin C and one third of the vitamin B_1. There is, in any event, little vitamin C in cow's milk, and not very much D. But even the small quantity of vitamin C in a pint bottle of raw milk was halved if the bottle was left on the doorstep in full daylight for half an hour; destruction was still more rapid in sunlight. Spray drying of milk led to a very small loss in nutritive value, of the same order as that caused by pasteurization. Roller drying brought about rather larger losses. Vitamin A and carotene, vitamin D and riboflavin suffered no loss during drying. Among other important points Dr. Kon emphasized the nutritional importance of the by-product from butter manufacture—skim milk. Dried skim milk ('National Household Milk') was an excellent food for all ages except early infancy.

The discussion on these two papers was opened by Prof. G. S. Wilson, who stressed the great difficulty that responsible medical men had in advocating the increased consumption of milk unless the latter had previously been efficiently pasteurized. He dealt with the human diseases that might be conveyed by raw milk, and exploded several of the arguments brought forward by the opponents of compulsory heat-treatment of milk. A lively discussion followed, in which Mr. A. L. Bacharach, Dr. H. E. Magee, Dr. N. S. Barron, Dr. W. A. Lethem, Captain H. Barkworth, Prof. J. R. Marrack, Dr. Kent-Jones and others took part. Perhaps too much attention was paid in the discussion to the pasteurization problem—the major facts concerning which are well known. In consequence, some of the important bacteriological and nutritional points made by the principal speakers in the afternoon session were crowded out.

In summing up, Prof. Kay stated that the real war-time problem was to get to every consumer the maximum quantity of safe winter milk, and he emphasized the great contribution that dairy farmers and those advising them and directing their efforts had made in maintaining the national winter milk supply during the War. There seemed to be no dissentients in this representative meeting of nutritionists (nearly three hundred were present during the afternoon session) to the view that general heat treatment of milk was highly desirable, in fact overdue, and that not least from the point of view of the true interests of the producer. It was also clear that the meeting fully agreed with the importance of increased consumption of liquid milk, and that the objective should be an average of not less than 1 pint per head per day. There was general agreement that one of the questions of greatest moment at present from the point of view of national nutrition was how the trend, clearly evidenced during the War, towards increased *per capita* milk consumption was to be maintained in the post-war period until this objective was achieved. Planning for increased post-war production and consumption should begin forthwith. There were three sides at least to this question, the producer's, the distributor's and the consumer's, and better technical training for all three, not excluding the frequently forgotten consumer, was urgently needed if this problem were to be solved in a reasonable time.

SOME CZECHOSLOVAK CONTRIBUTIONS TO CHEMISTRY IN THE NINETEENTH CENTURY

By DR. GERALD DRUCE

THE modern development of chemistry in Bohemia may be considered to have passed through five phases. These are: (1) an initial era closely associated with the Czech national revival movement and mainly concerned with descriptions and analyses of local natural resources; (2) advancement in teaching contemporary science; (3) improvement in analytical technique and corresponding progress in methods of research; (4) the period of Brauner's atomic-weight determinations and researches on the rare earths; and (5) varied research activities between 1918 and 1938.

The latter part of the fourth phase and the whole of the last one, when Czechoslovak chemists made some notable advances, fall outside the scope of the present survey. Similarly, the beginnings of the national revival (in which men of science played a leading part) date back to 1790, or perhaps to 1780, so that only the later, but scientifically more exact, work of the naturalists and chemists of this period will receive notice here.

The establishment of the Bohemian National Museum and the "Museum Society" in 1818 gave an impetus to the study of the sciences. Among the collections of local minerals presented to the Museum were specimens of unknown composition awaiting examination. There were also many economic native and exotic plants in the new herbarium, which soon included many thousands of specimens. Lastly, the medicinal qualities of the thermal and spa waters were then attracting attention and trustworthy analyses were urgently needed.

A typical mineral study was that of J. S. Presl on pribramite, a hydrated silicate of iron containing manganese and magnesium[1]. Many of these mineral analyses were made by men who were primarily geologists, like Prof. F. M. Zippe. Some of the Bohemian aristocracy were also interested in the natural sciences. In 1831, Count B. W. Berchtold analysed the efflorescence observed on bricks and known as "air salt" and referred to in his memoir as "Bruska salt" after the Prague suburb where it was collected[2].

In 1819, J. J. Steinmann prepared strychnine and isolated morphine[3], and a newly formed "Patriotic Economic Association" allocated funds for extracting it from poppies. The same body had also entrusted Prof. Mikan with the task of 'de-sulphurizing' coal. Presl and Steinmann (then professor of chemistry at the University of Prague) examined Kysibl Spa water[4], which later became a famous table water; Dr. A. Jungmann gave a comprehensive account of many other thermal waters[5]. When Berzelius visited Carlsbad in 1831 he examined the gas from the hot springs and estimated that it contained 1 per cent of nitrogen; it is mainly carbon dioxide, but is now known to contain about 1 per cent of inert gases, including radon.

There was a lack of laboratory facilities in Prague during the first quarter of the century and the few Czech chemists of note had little chance of making their work known except through German publications. Their only publications were the proceedings of the Bohemian Scientific Society (founded in 1775), a quarterly publication issued by the Museum, and Presl's periodical, *Krok*, which appeared at irregular intervals between 1821 and 1840. Though primarily a biologist, Presl devised a scheme of dry tests for the qualitative detection of metals, but it was not widely used. He wrote the first Czech text-book of chemistry, the inorganic part appearing in 1828 and the organic part in 1836[6]. It was a useful pioneer treatise that was superseded after 1841 by Prof. Amerling's[7]. This book, which recognized fifty-six elements, traced the development of crystallography and touched upon biochemistry. Thus, Amerling pointed to the constant occurrence of certain metals (potassium, calcium, magnesium and iron) and other elements (chlorine and sulphur) in plants and animals. He also appreciated the value of Faraday's work, and in surveying earlier developments he emphasized the importance of Black's discoveries with the alkaline earth carbonates.

These text-books gave Czech students a knowledge of chemistry in their own tongue. Previous lecturers like Mikan, Freysmuth, Neumann (Brauner's grandfather and author of a German "Lehrbuch der Chemie", 1810) and Balling (who studied both fermentation and metallurgy) had used German works. Noteworthy among these students was B. B. Quadrat, who, in 1844, investigated the double platinum cyanides[8] and prepared phenyl thiocyanate and studied its reactions and decomposition products[9]. Further contributions to organic chemistry were made at this time by Prof. J. Lerch, who isolated a number of monobasic acids (caproic, caprylic, capric, etc.) from various animal fats[10]. He also tried to elucidate the nature of the explosive, potassium carbonyl, sometimes formed during the preparation of potassium by dry distillation of the tartrate.

The outstanding figure of the third era of Czech chemistry was František Štolba (1839–1910), professor of chemistry at the Prague Polytechnic. He has been styled "the Czech Bunsen" on account of his influence and his extensive researches, though these never reached the magnitude or importance of those of the German chemist. From 1865 onwards Štolba published several hundred original papers, most of which were abstracted for the *Journal of the Chemical Society*, while the *Chemical News* referred to more than fifty of them. In 1877 Štolba founded the *Chemické Listy*, thus giving Czechoslovak chemists the opportunity to announce their discoveries in their own language.

In Štolba's first communication he demonstrated that both water and hydrochloric acid have an appreciable action on lead[11]. He proceeded to many analyses of local interest. Thus, he showed that the organic matter in water from Bohemian rivers was related to its calcium content. Another observation typical of the man was that platinum vessels lost in weight when heated in coal gas flames, though polished platinum lost less than unpolished. This was borne in mind later by Brauner, who not only kept his platinum ware highly polished but also always heated it inside another vessel. Štolba was one of the first to extract indium from zinc blende and tellurium from lead chamber mud, while another observation related to the identity of potassium chlorate crystals obtained either by fusion or by crystallization from aqueous solution. But his most important contribution to chemistry was his researches in the silico-fluorides.

Štolba prepared quantities of hydrofluoric and hydrofluosilicic acids and showed that the latter dissolve metals, for example, iron, evolving hydrogen. With this acid he made silicofluorides of cerium (from its acetate), cobalt (from the carbonate), ammonium (from the iron salt and ammonium chloride) and calcium (by heating together fluorspar, infusorial earth and hydrochloric acid). Štolba also noticed that beads of potassium silicofluoride heated in a blowpipe flame on platinum lost silicon fluoride and left a mixture of potassium fluoride and silicate. Curiously enough, Štolba's method for the analysis of silicate minerals began with sodium carbonate fusion, followed by re-fusion under salt. He left it to his colleague, the mineralogist Prof. E. Bořický, to 'open up' these minerals with hydrofluoric acid.

No account of Štolba's work would be complete without reference to his monograph advocating wider laboratory use of nickel. He emphasized its suitability for making crucibles, spatulas, tweezers, etc., and he indicated the precautions to be observed. He was also alive to the possibilities of aluminium, which was just becoming available in the 'eighties.

Among other noteworthy chemical discoveries made by Czech chemists in the middle of the last century are those of Prof. Karel Preis, lecturer at Prague Polytechnic and later founder of the Sugar Research Institute. Before devoting himself to technological researches he studied the action of iodine on unsaturated organic compounds, made the bromides of tin and some double salts in a pure state and came across a curious double sulphide of iron and potassium[12]. With Dr. B. Rayman he oxidized cholesterol and some derivatives with nitric acid. That more Czechs did not interest themselves in organic chemistry at this time is difficult to explain. Prof. A. Bělohoubek, contemporary with Štolba, showed that pure methyl alcohol never gave chloroform with bleaching powder. From a comprehensive survey of organic compounds he concluded that the richer these are in oxygen the more soluble they are, while liquids are mutually soluble the more similar their structure.

During the last quarter of the century Czech inorganic chemists made good progress. It was dominated by the work of Brauner and his collaborators, which overshadowed the less spectacular but still important contributions made by Wald and Stoklasa.

Prof. F. Wald was a physical chemist who maintained that stoichiometrical laws are deducible without recourse to any atomic hypothesis. In 1887, independently of J. W. Gibbs, he propounded a theory of phases on the basis that all substances that mix continuously and homogeneously constitute a single phase. Therefore, gases exist as one phase only, since two or more gases or vapours never form sharp boundaries. Liquid phases are more numerous, while with solids it is still more difficult to characterize one or more phases. It would be difficult to summarize Wald's views in a few lines[13], but his definition of an element may be taken as typical:

"Amongst chemical individuals there is a group of substances which possess a remarkable property. From them may be prepared by chemical reactions other pure substances, yet they are never alone a product of other reactions. Such bodies are called elements. If reactions which are described in a three-membered equation did not exist, elements would remain unknown to us; no substance of a reaction, in which a certain number of reactants gives the same number of resultants, can be regarded as a part of the others. Our knowledge as to the number of elements remains, however, provisional as we have no guarantee that the substances now regarded as elements will not be shown to be decomposable and interchangeable."

Ostwald, in his Faraday Lecture in 1904, referred to Wald's views in the following words:

"The question whether it is possible to deduce the stoichiometrical laws without the help of the atomic hypothesis has only been raised by other investigators in order to deny the possibility. So far as I am aware there exists only one man (Wald) who has worked on the question with the earnest hope of obtaining an affirmative answer . . . to him I owe first the idea that the definition of substances and elements is in a certain sense arbitrary, although very helpful and convenient. This definition is a condensed expression of our methods of separating and purifying these bodies. While, generally speaking, every solution has the same claim to be investigated as these bodies, the latter soon distinguish themselves as standards to which all other cases may be referred. To Wald I owe further the idea that the conception of a phase is a far more general one than that of a substance, and that the deduction of the laws governing the nature of substances must start from the conception of a phase. . . ."[14]

Stoklasa's researches were partly analytical and partly biochemical. Among other matters he showed that both iron and phosphorus are essential elements for the formation of chlorophyll in plants. In his lengthy study of lecithin he found that it decomposes in the absence of phosphates and that plants lacking phosphates retrogress for this reason.

Brauner's work, lengthy and important though it was, can only receive very brief notice here. It began in 1877 with his observations on beryllium and had for its main object the substantiation of Mendeléeff's Periodic Law[15], the great value of which Brauner was one of the first to appreciate. Most of his atomic weight determinations and his separations of the rare earth elements were made before 1900, and indeed Mendeléeff stressed their importance so early as 1889 in his Faraday Lecture[16]:

"The Periodic Law, as Brauner repeatedly insisted, was against the formula, Be_2O_3. It required the formula BeO, *i.e.* an atomic weight of 9. . . . I consider the confirmation of Brauner's view as important in the history of the law as the discovery of scandium."

Science is international in its ramifications, and the discoveries of savants of one nation influence and inspire the work of others in distant lands. Not only did Brauner make contact with Russian men of science, but he also established connexions with British and American chemists; and at the close of the nineteenth century many young Czech chemists, beginning their careers, spent part of their student or post-graduate years abroad. At this time, Štěrba-Böhm was collaborating with Brauner in further studies of the rare earths, while Votoček had begun his life-work on the less common sugars. After closely studying arabinose he examined rhodeose, a methylpentose that he had isolated from the glycoside convolvulin[17].

In chemistry, as in other sciences, Czechoslovaks made notable advances during the nineteenth century. This work continued to expand and extend until 1939, and when they are able to resume their work for the progress of mankind it can be confidently predicted that they will contribute again to the advancement of chemistry.

OBITUARIES

Dr. C. J. S. Thompson, M.B.E.

DR. C. J. S. THOMPSON, who died recently, was born at Liverpool in 1862. As a young man he studied chemistry and pharmacy and became interested in the historical aspect of these subjects. In 1898 his close association with what was ultimately to become the Wellcome Historical Medical Museum commenced. From this date he played an active part in assisting Sir Henry Wellcome in the work of collecting, classifying and assembling the ever-increasing store of material. In 1913, he became the first conservator of the Wellcome Historical Medical Museum.

Thompson travelled widely and was a successful collector: he was much interested in the literature of his subject, and played an important part in establishing the large research library attached to the Museum. In the International Congresses of the History of Medicine he played a prominent part, more especially in the Congress held in London in 1922. He was a prolific writer with a wide knowledge of his subject, a ready pen and a popular style. He covered a large field in his numerous articles and books, many of which were popular in character and dealt with such subjects as alchemy, crime, quackery, apparitions, monsters, magic and love. He also compiled in collaboration with Sir D'Arcy Power a most useful "Chronologia Medica".

His connexion with the Wellcome Museum terminated in 1926, and in the following year he was elected honorary curator of the Historical Collection of the Royal College of Surgeons. His "History and Evolution of Surgical Instruments", published in the United States in 1942, was opportune, for in May 1941 much of the collection had been destroyed by enemy action.

During the War of 1914–18 he was in charge of an auxiliary military hospital at Harrow, for which work he was awarded the M.B.E.

Thompson was a great enthusiast, an indefatigable worker, and a good organizer. For such a man retirement is merely the opportunity for further work and, to the end, he was busily occupied with the subject which he had made so peculiarly his own. He did much to popularize a branch of medicine which in Great Britain has never received the recognition it deserves. S. H. DAUKES.

Dr. R. W. Gray.

ROBERT WALKER GRAY, born at Peterhead, Aberdeenshire, in 1864, came of whaling stock. His grandfather and his father were well-known skippers in the Peterhead whaling fleet, and the latter, doubtless inspired by the example of the Scoresbys, made many records of his observations in the Arctic seas. David Gray's "Notes on the Greenland Whale" appeared in annual reports of the Scottish Fishery Board and elsewhere, accounts of the year's whaling in the *Buchan Observer*, and Southwell made use of some of his information in his articles on sealing and whaling. It was natural, therefore, that one of the sustained interests of the son, R. W. Gray, should be in whales and whaling. His name appears in the roll-book of the natural history class at the University of Edinburgh for the session 1887–88, when he was in his twenty-third year, and he graduated in medicine at that University in 1892. Having already made several voyages to the Greenland Sea, he became surgeon upon his father's whaler, *Eclipse*, at a time when the Peterhead whaling was all but extinguished, and his subsequent experience included voyages with the Orient Line as medical officer, the study of sleeping sickness in Africa, and a long period of general practice in towns on the south coast of England.

Since his earliest accounts of voyages to the Greenland Sea appeared in the *Zoologist* in 1887 and 1889, Dr. Gray continued to publish articles bearing upon the history of the whale-fishery and on whales and their habits. He contributed the account of "Whale Fisheries" to the ninth edition of the "Encyclopædia Britannica", and his description of the rise and decline of the "Peterhead Sealers and Whalers" in the *Scottish Naturalist* of 1932 and 1933 was a valuable contribution to the history of the whaling industry. Dr. Gray's knowledge of the literature of whaling was thorough, and he made good use of it and of his own experiences in discussing, in the *Naturalist* and in occasional letters to NATURE, debated points concerning the physiology of whales.

Dr. Gray had a quiet unassuming manner and a mind richly stored with memories of his adventures in the Greenland Sea and Davis Straits. Having retired from medical practice, he died early in July in Exeter, after a short period of failing health, in his seventy-ninth year. JAMES RITCHIE.

WE regret to announce the following deaths:

Dr. H. C. Bumpus, director of the American Museum of Natural History, New York, during 1902–11, on June 21, aged eighty-one.

Mr. F. J. Cleminson, honorary director of research, Ferens Institute of Oto-laryngology, Middlesex Hospital Medical School, on August 21, aged sixty-five.

Mr. Arthur S. Newman, the well-known camera designer and photographic expert, on August 12, aged eighty-two.

Prof. F. Schlesinger, emeritus professor of astronomy in Yale University, on July 10, aged seventy-two.

NEWS AND VIEWS

Carnegie United Kingdom Trust

The twenty-ninth annual report of the Carnegie United Kingdom Trust covering the year 1942 shows that the operations of the Trust have been more concerned with the development or the completion of old schemes than with the initiation of new ones. In regard to youth services, the system of club equipment grants has been continued in England, Wales and Scotland, and has also been extended to Northern Ireland. The year's payments amount to £5,695 and substantial sums are still outstanding in respect of promises not yet taken up in full; the 1942 promises at December 31 stood at £12,168. Shortage of equipment due to the supplies situation and the scarcity of trained leaders are likely to present serious difficulties to any large expansion of the youth services at present. The limited revival of the former club library policy has met with very encouraging responses, and grants in aid of the headquarters administration of the national associations of boys' clubs, girls' clubs and young farmers' clubs were maintained in 1942 at the same rate as in the previous year. Notice of the discontinuance of these grants has now been given, but further assistance has been promised to the Eighteen Plus movement during the three years 1943–45. Grants for the training of leaders, of £1,200 to the National Association of Girls' Clubs for local supervisors of training and £1,000 for bursaries, were continued from 1941. Grants were also made during 1942 in aid of the administration of the Land Settlement Association, the Museums Association, the National Council of Social Service and the Rural Development Council of Northern Ireland, and towards the maintenance of the three central libraries. In regard to music and drama, the work of the Musical Education Committee has continued on the same plan as in 1941 but on a larger scale. The work of the Joint Committee for Drama also showed an increase in expenditure, and the report comments on the remarkable way in which musical and dramatic activities are not merely surviving the War but even extending and fortifying themselves.

Utilization Investigations of Forest Products

As during the War of 1914–18 so in the present War, the utilization of forest products has assumed a first-class importance in India. During the War of 1914–18 the exports from the Indian forests, mainly timber and forage, went chiefly to the Middle East. But India herself had to become self-supporting in several commodities such as, for example, soap, matches, bobbins for weaving and even to a greater extent railway sleepers, when these products could no longer reach her by import. This state of affairs has repeated itself during the present War, but has become more exacting through the greater demand on India to provide war supplies for her own needs and including those of a rapidly expanding modern army. This position fully explains the reason for the inevitable expansion of the work of the Utilization Branch of the Dehra Dun Forest Research Institute. Research on timber-seasoning kilns has already been dealt with (see Nature, July 25, 1942, p. 127). Indian Forest Leaflet No. 34, Utilization (1943), "Types of Timber Seasoning Kilns suitable for drying Indian Woods", revises Leaflet No. 11, issued on the subject. Leaflet No. 33 (1943) deals with the detailed design of timber roof trusses made with disk dowel joints. Timber structures fitted in this fashion have not previously been used in India. The data incorporated in the leaflet are the result of actual tests carried out in the laboratories of the Institute.

Indian Forest Bulletins, Utilization, Nos. 114 and 117 (1943) discuss the "Treatment of Green Hollong (*Dipterocarpus macrocarpus*) Sleepers" and the "Testing of and Improvement in Design of Packing Cases". The green hollong sleepers were treated with a mixture of creosote and fuel oil; by conditioning the sleepers by steaming and vacuum or the Boulton process, or a combination of both, they could be satisfactorily treated, on an average 30 per cent moisture being lost. The packing case investigation was carried out at the instance of the Ordnance Stores Department. Cases for packing medical stores were the ones to which the investigation was confined. Three types of cases were examined, and the improvements proposed are discussed in the bulletin.

Our Knowledge of the Physical World

Dr. A. C. Ewing, in an article entitled "Knowledge of Physical Objects", has discussed the question, "How can we justify the claim to know the physical world?" (*Mind*, April 1943). He first considers the contention that it is meaningless to entertain a *general* doubt about such knowledge because there are no possible experiences which could cast doubt on *all* physical propositions, only on some. He answers it by pointing out that dreams and illusions are the experiences on which the general doubt is based, and even though they are not conclusive evidence, the doubt has meaning by reference to them. This was a point well worth making. He next examines Prof. Moore's view that we can know with certainty something which it is both logically possible might not be true and also logically possible we might be wrong in thinking we knew. Our knowledge of physical objects is of this kind, according to Moore, and we know them without knowing how we know them. As Moore does not hold that we know physical objects directly, it seems possible to raise a doubt about our knowledge by pointing out that induction, by means of which this knowledge is established, cannot yield certainty. Briefly, Moore's answer to this is that the proposition that inductive argument cannot yield certainty is itself *less* certain than the proposition that he knows there is a chair.

The author develops his own position from this point by urging that strictly we can only speak of knowing that *S* is *P* where "*S* is *P*" is *objectively* as well as subjectively certain; but that we commonly say we 'know' that *S* is *P* where we are practically certain, though error is theoretically possible. In the strict sense we do not know that there are physical objects; in the other sense we do. Such knowledge is based on induction and therefore it must be admitted that any particular proposition which we know can by further evidence be rendered more certain than it is at any particular time. This is the Achilles' heel of the author's view. The present writer cannot believe that the existence of the table on which he wrote these notes, and on which a short time ago his supper was laid, can be rendered more certain. The distinction drawn by Dr. Ewing does not solve the problem. It simply takes us back to the discarded view that the existence of physical objects cannot be known, though it can be rendered highly probable.

Vital Statistics of Scotland

According to the quarterly return of the Registrar-General of Scotland, 1942 was a very healthy year, as is shown by the fact that the death-rate from all causes was 13·0 per 1,000 of the population, or 1·5 below the corresponding rate for 1941 and 0·7 below the average for the quinquennium 1936–41. The birth-rate was 18·1 per 1,000, or 0·2 above the average for 1941 and 0·5 above the five-year period. Both infantile mortality and maternal mortality showed very satisfactory rates, the former being 69 per 1,000 live births and the latter 4·0 per 1,000 total births, which was the lowest rate on record for about four decades. The deaths from the principal epidemic diseases were the lowest on record, amounting to 1,060. As regards the chief chronic diseases with a high mortality, the death-rate from all forms of tuberculosis was 80 per 100,000. Though there was a decline in non-respiratory tuberculosis, especially in the age-group fifteen to twenty-five, there was a definite rise in the respiratory tuberculosis death-rate. Increase in the death-rate for syphilis was shown mainly by an increase in aneurysm and congenital syphilis. The death-rate from malignant disease was 171 per 100,000, which represented an increase above the 1941 rate. On the other hand, there was a definite decline in the death-rate for cardiac and respiratory diseases apart from tuberculosis and malignant disease.

Syphilis in the United States

In a recent paper (*J. Amer. Med. Assoc.*, **122**, 365; 1943) Dr. W. G. Smillie maintains that the incidence of syphilis among white men in the greater part of the United States is low, and that it is limited for the most part to the lowest classes of society, so that it has become a disease largely of the ignorant, the careless, the criminal and the social outcast. Syphilis, however, is more than ten times as prevalent among the Negroes as among white persons. In recent examinations for army service, the incidence of syphilis among whites was 0·2 per cent, as compared with 11·2 per cent among Negroes.

Tuberculosis in Buenos Aires

According to Dr. Alejandro A. Raimondi (*J. Amer. Med. Assoc.*, **208**, 121; 1943), director of the Municipal Centre of Buenos Aires for a Campaign against Tuberculosis, there were 2,708 deaths from that disease in Buenos Aires in 1941. The increase in the disease is due to the influx of tuberculous subjects from the provinces. The routine practice of taking skiagrams of children has resulted in finding tuberculosis where it was not suspected and also in preventing the spread of the disease. X-ray examination of the chest of apparently normal persons has yielded good results. Tuberculosis has been found in only five cases (1·3 per cent) in a group of 384 students and in only twenty-five cases (3·02 per cent) in 826 applicants for municipal posts.

Agricultural Research Council Appointments

The Committee of the Privy Council for Agricultural Research has appointed the Right Hon. the Earl De La Warr to be chairman of the Agricultural Research Council in succession to the late Sir Thomas Middleton. The Committee has further appointed Prof. I. de Burgh Daly to be a member of the Agricultural Research Council in succession to Sir Joseph Barcroft, whose term of office as a member has expired.

Library Stocks of Periodicals

Referring to the letter on "Library Stocks of Periodicals" published in Nature of July 24, Mr. C. C. Barnard writes: "I inadvertently failed to appreciate the proposals of a committee of the Association of Special Libraries and Information Bureaux, which has under consideration the preparation of a Union Catalogue of Periodicals in British Libraries. This Committee proposes at present to limit its plan to the compilation of a consolidated check list composed of entries in the 'World List of Scientific Periodicals', the 'Union Catalogue of Periodical Publications in University Libraries', and the relevant section of the 'British Museum Catalogue'. The work which it contemplates should be of assistance in the accomplishment of the larger scheme which I outlined."

Wellcome Junior Fellowship

The Joint Advisory Committee of the Wellcome Foundation and the Veterinary Educational Trust has awarded the first Wellcome Junior Fellowship to Mr. John Lochiel McGirr. The fellowship is tenable for one year at £400 per annum and is subject to renewal for a further period of one or two years at the discretion of the Advisory Committee. Another fellowship of equal value will be awarded in April 1944. The award to Mr. McGirr represents the first result of the recent foundation of the Veterinary Educational Trust.

The Night Sky in September

Full moon occurs on September 14d. 03h. 40m. U.T. and new moon on September 29d. 11h. 29m. The following conjunctions with the moon take place: Sept. 2d. 00h., Mercury 7° S.; Sept. 20d. 03h., Mars 4° N.; Sept. 21d. 05h., Saturn 3° N.; Sept. 25d. 14h., Jupiter 0·3° N.; Sept. 26d. 16h., Venus 8° S. The following occultations of stars brighter than magnitude 6 take place: Sept. 8d. 21h. 02.4m., 15 Sgr (*D*); Sept. 10d. 21h. 27.3m., σ Cap (*D*); Sept. 26d. 11h. 08.2m., α Leo (*D*); Sept. 26d. 12h. 12.1m., α Leo (*R*). The times are given for Greenwich and *D* and *R* refer to disappearance and reappearance respectively. Mercury, an evening star at the beginning of the month, sets a quarter of an hour after the sun on Sept. 1. The planet is approaching the sun and is in inferior conjunction on Sept. 24. Venus is in inferior conjunction with the sun on Sept. 6. At the middle and end of the month the planet can be seen as a morning star, rising at 4h. 43m. and 3h. 20m. respectively. Mars, in the constellation of Taurus, is an evening star and sets at 13h. 20m., 13h. and 12h. 32m. at the beginning, middle and end of the month respectively. Jupiter is a morning star, rising at 3h. at the beginning and 1h. 33m. at the end of the month. Saturn, in the constellation of Taurus, is a morning star, rising at 22h. 08m. in the middle of the month. Times are given approximately for the latitude of Greenwich. The Autumn Equinox commences on Sept. 23d. 22h. The longer evenings provide opportunities for those who are interested in observational work, and many interesting objects are within the range of a small telescope.

X-Irradiation of Rabbit Spermatozoa *in vitro*

The classic experiments of Hertwig on the X-irradiation of frog spermatozoa were recently extended by Rugh[1], who reported that exposure of the spermatozoa to doses from 15 r. to 10,000 r. caused a progressive increase in embryonic mortality; at the higher dosage only 1·6 per cent of the embryos hatched. Further increase of the dosage, however, increased the number of viable embryos; at 50,000 r., 90·5 per cent hatched. These embryos were morphologically uniform and very similar to haploids produced by other means. Rugh concluded that with the higher doses the spermatozoa, which showed normal motility, were able to penetrate the egg, but were unable to effect syngamy, so that the development initiated was parthenogenetic.

Comparable effects with the small doses have been demonstrated in mammals. Doses of 800 r. to mice[2] and 1,000 r. to rats[3] do not diminish the capacity of the existing spermatozoa to effect fertilization, but early mortality among the embryos reduces litter size. The mammalian work on X-rays, with the solitary exception, so far as we know, of some inconclusive experiments by Asdell and Warren[4], has involved the mating of irradiated males, a technique which has several disadvantages. Pincus and Enzmann[5], however, carried out a few experiments on rabbits by inserting into the Fallopian tube spermatozoa which had been exposed *in vitro* to ultra-violet irradiation, and obtained some rather inconclusive evidence of penetration and activation of the eggs without syngamy. We have now carried out, also on rabbits, experiments involving the *in vitro* X-irradiation of semen, followed by artificial insemination. In addition, the induction of superovulation by the injection of gonadotrophin has proved most useful in augmenting the number of eggs used for the study of the segmentation stages.

The females were killed and the tubal or uterine contents examined at various times up to 40 hr., at 9 days, or at 28 days after ovulation. Results with the various dosages were briefly as follows:

50 *r. and* 100 *r.* The great majority of the eggs segmented normally and normal implantations at 9 days and normal young at term were also obtained.

250 *r. and* 500 *r.* Most of the eggs were segmenting normally at 40 hr., but there was a definite increase in the percentage of those which were retarded or arrested. Normal implantations and apparently normal young at birth were obtained, but in small numbers.

1,000 *r.* The great majority of the eggs had started to divide but had no more than 10 cells at 40 hr.; less than 3 per cent were apparently normal. No implantations at 9 days or young at term were obtained with this or any higher dose.

2,500 *r.*–10,000 *r.* More than 70 per cent of the eggs recovered at 40 hr. had started to segment, but most of these were in the 3- or 4-cell stage. None was segmenting normally.

25,000 *r.*–50,000 *r.* Most of the eggs had made a single division only at 40 hr., and were arrested in the 2-cell stage.

100,000 *r.* Only 8 of the 70 eggs obtained at 40 hr. had divided, and 6 of these were in the 2-cell stage.

Cytological examination was made of many of the eggs fertilized by spermatozoa receiving between 500 r. and 100,000 r. The presence of male nuclei within the cytoplasm of the egg showed that penetration had been effected at all dosages. Spermatozoa were abundant in the perivitelline space and zona pellucida at all dosages up to 50,000 r., but at 100,000 r. very few were seen. Delay in migration and vesiculation of the male nucleus was observed at all doses from 1,000 r. to 10,000 r. and constituted the earliest indication of any organic change caused by irradiation of the spermatozoa. Cytological evidence of damage to the male nucleus appeared only with doses of 10,000 r. and above. At lower doses the nuclei were single and oval or spherical, while with the higher doses the majority were hypertrophied and lobed.

At the stage of fusion of the pronuclei the effects of various dosages may be summarized as follows:

1,000 *r.* Syngamy was complete with no outward sign of irregularity in the male pronucleus.

10,000 *r.* Syngamy took place, but the male pronucleus was very irregular and hypertrophied, and the chromosomes remained dispersed.

25,000 *r.* Syngamy might take place, but in some eggs the occurrence of polyspermy produced derangement in the distribution of the chromosomes. Cytoplasmic division and separation in these cells might be incomplete.

50,000 *r.* Syngamy occurred, but the formation of the male chromosomes was delayed or suppressed, so that zygotic combination was weakened. Because of the delay in polar migration of the chromosomes the cleavage spindles were irregular.

100,000 *r.* Extrusion of the polar bodies and migration of the male nucleus was observed, but no syngamy in any of the eggs studied. However, the recovery of 2-celled eggs with diploid chromosomes showed that the absence of syngamy may not be constant. The occurrence in one egg of a single segmentation spindle with haploid chromosomes suggested that spermatozoa exposed to 100,000 r can sometimes activate the egg without fusion of the pronuclei. No evidence of continued gynogenetic development was, however, obtained.

A full account of the experiments outlined above is being prepared, but it may be noted here that the technique of semen collection, artificial insemination and, where appropriate, induction of superovulation offers exceptional facilities for the type of work described above, and is being used by us for the study of the effects of chemical and serological as well as of physical agents on the physiological and genetic properties of mammalian sperm.

We are much indebted to Dr. W. V. Mayneord who kindly allowed the irradiations to be carried out in the Department of Physics of the Royal Cancer Hospital.

Possible Role of Birds in the Maintenance of Yellow Fever in West Africa

In 1936 it was shown that the blood of monkeys from endemic yellow fever zones in Africa contained immune bodies to the yellow fever virus, as judged by the intraperitoneal mouse protection test: the sera of monkeys outside the endemic zone did not contain immune bodies[1]. These results have since been confirmed by other workers. At the same time, the blood of a sheep from the Gambia was found to possess virucidal bodies against the yellow fever virus. Since then virucidal bodies have been found in the blood of cattle, sheep, dogs, pigs and a camel: the significance of these findings in domestic animals awaits further study, since virucidal bodies were present in the blood of certain domestic animals living outside the commonly accepted yellow fever zone.

Although there is highly suggestive evidence that monkeys may act as an alternative host to man in maintaining yellow fever in Africa, the monkey population is not large, nor is there evidence that monkeys migrate over great distances.

A search has therefore been made for other possible hosts sufficiently numerous to maintain the virus in the absence of man. The sera of a number of animals and birds have been examined from the Gold Coast. Although no epidemic has been reported in this Colony since 1937, single sporadic cases have occurred every year, and immunity surveys in children show that the number of cases reported bears no relation to the number of children giving positive results. Apart from monkey sera giving positive results, a rodent, a Cutting grass *Thryonomys swinderianus*, one of five examined, has been found to possess virucidal bodies to yellow fever virus in its blood. The sera of civet cats, giant rats, bush-tailed porcupines and royal pythons have been negative. More striking results have been obtained with the sera of wild birds. Of forty birds examined four have shown virucidal bodies to the yellow fever virus. The positive birds were a buff-backed heron *Bubulcus ibis ibis*, one of four examined, an African barn-owl *Tyto alba affinis*, one of three examined, and a Senegal kingfisher *Halcyon senegalensis senegalensis*, the only specimen examined. All these birds belong to common and widely distributed species.

Further work, which is at present proceeding, is required to determine the exact significance of the virucidal bodies contained in the sera of these birds. Should further evidence show that the virucidal action is due to the development of immune bodies as a result of previous infection with the yellow fever virus, a clue may have been found to the maintenance of yellow fever in Africa, and possibly also an explanation of the occasional occurrence of sporadic infections in man at considerable intervals in space and time. Much further knowledge is required of the migration of birds within Africa. Thus the Senegal kingfisher is said to be migratory in Darfur, but there is no record of its migration in the western part of its range. The buff-backed heron, however, is known to have an extensive migratory range from the southern edge of the Sahara to the Guinea coast, thus traversing the endemic yellow fever zone from north to south. This bird is closely associated with man and with cattle.

It will be recalled that in America birds appear to play an important part in the maintenance of the eastern and western strains of equine encephalomyelitis virus: the same may be true of the yellow fever virus in Africa.

Synergistic Effect of Para-aminobenzoic Acid and Sulphapyridine on Penicillin

A solution of sodium penicillin, containing 1,200 units per c.c., was tested for bacteriostatic activity against *B. subtilis* and found to be active in a dilution of 1 : 100 in a synthetic medium containing 0·1 per cent acid hydrolysed casein[1].

When *p*-aminobenzoic acid was added to the medium in dilutions of 1 : 2,500–1 : 10,000, the inhibitory effect of penicillin on the test organism was increased to a titre of 1 : 6,000. An increase in the activity of penicillin on addition of *p*-aminobenzoic acid was also observed with glucose broth as nutrient medium. A similar, though less marked, effect on penicillin activity was shown by *p*-aminobenzoic acid against *Staphylococcus aureus* (strain 663) in the same synthetic medium containing hydrolysed casein. Using a solution of sodium penicillin with a titre of 1 : 40,000, the effect of *p*-aminobenzoic acid (added in a dilution of 1 : 2,500–1 : 50,000) was to increase the titre to 1 : 75,000-1 : 100,000. *p*-Aminobenzoic acid had no effect on the activity of penicillin solution against *Streptococcus hæmolyticus* (strain 618, group *A*).

p-Aminobenzoic acid did not increase the activity of penicillin in concentrations greater than 1 : 1,000.

The enhancing effect of sulphapyridine on penicillin was more marked than that of *p*-aminobenzoic acid. Sulphapyridine, which, when tested against staphylococcus (strain 663), showed no inhibition of growth in digest broth in dilutions up to 1 : 2,000, was added in dilutions up to 1 : 50,000 to a solution of sodium penicillin, which inhibited at 1 : 30,000; inhibition occurred up to a titre of 1 : 70,000. When *p*-aminobenzoic acid was added in a dilution of 1 : 20,000 to the penicillin solution containing sulphapyridine (1 : 5,000), inhibition occurred at 1 : 40,000.

The experiment was repeated using 1 per cent glucose broth, and the activity of penicillin against staphylococcus (strain 663) and streptococcus (strain 618) was again shown to be enhanced in presence of sulphapyridine. A solution of sodium penicillin inhibited staphylococcus at a titre of 1 : 20,000; in presence of sulphapyridine (in dilutions up to 1 : 50,000) the solution inhibited at a titre of 1 : 50,000. Similarly, a solution of sodium penicillin inhibited streptococcus (strain 618) at dilutions up to 1 : 50,000; in presence of sulphapyridine (in dilutions from 1 : 5,000 to 1 : 50,000), the same penicillin solution inhibited streptococcus at a dilution of 1 : 100,000. Sulphapyridine itself showed inhibition only at a concentration of 1 : 2,500. A dilution of 1 : 5,000 had no effect on the growth of steptococcus.

Thus, the inhibitory effect of penicillin in presence of small quantities of sulphapyridine, which, *per se*, are insufficient to show any effect on staphylococcus or streptococcus, is at least doubled.

Having shown *in vitro* the synergistic effect of penicillin and sulphapyridine, their action was investigated *in vivo* in mice, and some preliminary results confirming the *in vitro* experiments are recorded.

Groups of six mice were treated with (*a*) small doses of sulphapyridine insufficient to give any protection either against streptococcus or staphylococcus, (*b*) small doses of penicillin, (*c*) both substances simultaneously in these doses.

Sulphapyridine was injected in 0·5 per cent suspension and given in doses of 0·1 c.c. twice daily intraperitoneally. A solution of sodium penicillin (about 90 units per c.c.) was injected in 0·2 c.c. doses, also twice daily. Treatment was continued for four days and the results were recorded at the end of seven days from the commencement of treatment. Each group of mice was infected, at the beginning of treatment, with 1 × 10^6 streptococci (strain 618) or with 500 × 10^6 staphylococci (strain 663). The table shown below gives the number of survivals.

	Streptococcus hæmolyticus							*Staphylococcus aureus*						
Days . .	1	2	3	4	5	6	7	1	2	3	4	5	6	7
Sulphapyridine	6	2	1	1	1	1	1	0	0	0	0	0	0	0
Sodium penicillin . .	6	5	2	2	1	1	1	4	4	2	2	1	1	1
Sulphapyridine + sodium pen. . .	6	6	6	6	6	4	4	5	5	4	4	4	4	1
Control Strept.	0	0	0	0	0	0	0	1	0	0	0	0	0	0
					↑ Treatment stopped							↑ Treatment stopped		

The results show the increased protective effect of both substances given together. This might give an even greater survival rate if treatment were extended for more than four days.

The increased activity of both substances when applied simultaneously may be due either to the synergistic action of the two substances on the micro-organism, or less probably to a chemical reaction between the sulphonamide and the penicillin. These possibilities are being investigated.

We thank the directors of the Therapeutic Research Corporation of Great Britain, Ltd., for permission to publish this communication.

It should be pointed out that penicillin is not yet available for general use.

The Development of the Angoumois Grain Moth (*Sitotroga cerealella* Oliv.)

THE Angoumois grain moth has been known as an important pest of stored and field grain since the time of Réaumur[1], and it has possibilities as a laboratory insect. A search through the literature[1–9] revealed, however, that its life-history has apparently never been worked out in detail. A knowledge of the number and duration of the larval instars at 30° C. and 70 per cent relative humidity was required for a quantitative study of populations of this species, and some observations were consequently made under these experimental conditions.

One freshly laid egg was introduced into each of a hundred small vials. The latter were then examined daily until the eggs hatched, when one gram of fine wheat flour was added to each vial. The flour had been obtained from a local miller and sieved through No. 52 (extra quadruple) silk bolting cloth. The larvæ of Sitotroga will develop quite successfully in this medium, although mortality is high. The contents of each vial were gently sieved daily, and moults deduced from the discovery of cast skins and checked by measuring the width of the head capsule. Four larval instars were found, followed by a pupa, from which the adult eventually emerged. Mature larvæ were found in hollows in the flour, lined by a delicate cocoon, against the glass side of the vial. They became quiescent for about two days before metamorphosis. The average duration and body measurements of each instar are shown in the accompanying table. The average ratio of increase in each instar, used in the calculations from Dyar's rule, was 1·7.

Instar	Duration in days		Width of head capsule (mm.)	Width of head capsule, calculated from Dyar's rule	Approx. width of thorax (mm.)	Approx. total length (mm.)
	Mean	Range				
Egg	3	2– 7				
First larval	6	4–10	0·15–0·19		0·22	1·2
Second larval	6	4–10	0·28–0·32	0·29	0·38	1·6
Third larval	5	2– 9	0·47–0·53	0·51	0·80	4·3
Fourth larval	7	6–12	0·76–0·84	0·85	1·65	7·0
Pupa	5	4– 7				
Total	32	30–40				

The body measurements are each the averages of observations of five individual larvæ, and the developmental periods the averages of observations of at least twenty-one individuals. Only twenty-two adults emerged from the hundred original eggs, twenty having been killed to make body measurements and fifty-eight dying. Twenty-one of these adults emerged within ten days of each other, while one did not emerge until the seventy-second day after oviposition. Such prolonged development has been observed by other authors[2,3], but under uncontrolled conditions of temperature and humidity. This abnormal individual was disregarded in calculating the average duration of the different instars. All its larval instars were longer than the average, while the pupal period was of average duration. The moths usually mated almost immediately upon emergence, and the pre-oviposition period was approximately one day. The average generation time was thus thirty-three days.

This is a suitable opportunity to correct an omission from a previous paper[4]. In line 11 from the bottom of p. 330, for "insects per grain" read "insects per grain, at which densities the average longevity was 6·6 and 4·4 days, respectively".

Frictional Properties of Metallic Films

DR. HUGHES's recent remarks[1] would appear to be based on the three wrong premises that, first, films of soft metals wiped on to steel surfaces on which a loaded steel ball was made to rotate[2] never decreased the electromotive force ; secondly, the interpretation of earlier observations[3] on the frictional behaviour of such films on a copper surface made on the Bowden-Leben apparatus had been criticized ; and thirdly, frictional decreases due to these films should be taken as an indication that changes in the ploughing contribution to the frictional force were immaterial when such decreases were observed "during the *first* slide" with the Bowden-Leben apparatus.

Dr. Hughes, it seems, has overlooked the difference of the results obtained with the revolving sphere and metallic films wiped out once under 'dry' conditions, and the other time in the presence of an oil. It has been stated[2] that "Even in those cases in which the films reduce the electromotive force under 'dry' conditions, they do not appear to function as a lubricant for a brief interval until normal lubricating conditions are re-established".

The results listed in Table 2 (ref. 3) allow of no misrepresentation, and it is the conclusion drawn by Dr. Hughes and his colleagues[3] from a comparison of Tables 1 and 2 (ref. 3) that "in a heterogeneous bearing metal the soft phase wipes out over the hard phase during sliding": that is regarded as conjectural.

There is a difference between wearing in a groove on the surface of a block of compact metal and of ploughing a track on a film of wiped-out softer metal of sufficient thickness to carry the main portion of the normal load. To choose a homely analogy, it is qualitatively the same difference as between scribing a line with the end of a walking-stick once on a hard rolled gravel path and then on the same path covered with a reasonable amount of loose gravel. One is bound to experience a frictional decrease "during the *first* slide" in the latter case. Just on account of the ploughing action would one expect a smaller friction "during the *first* slide" in the presence of a wiped-out metallic film, the friction remaining little changed by successive strokes in the same track, *until* the wiped-out films would be penetrated, when the friction would be expected to *rise* to values approaching that of steel on the substrate—copper, for example—and on further continued successive strokes in the same track a renewed decrease of the friction would be expected with the wearing in of *one* groove in the substrate.

There seems to be general agreement[1,2,4,5] that ploughing is the essential feature of the Bowden-Leben apparatus when the hemisphere is the harder of the two friction elements, since Dr. Hughes's claim has remained unsubstantiated "that the grooving contribution to the friction, which must evidently be present to a certain extent, is small compared with the contribution of adhesive forces".

ROBERT SCHNURMANN.

Physics Department,
Manchester Oil Refinery, Ltd.,
Manchester.
June 11.

---

[1] Hughes, T. P., NATURE, 151, 533 (1943).

[2] Schnurmann, R., NATURE, 151, 420 (1943).

[3] Heaton, J. L., Bristow, J. R., Whittingham, G., and Hughes, T. P., NATURE, 150, 520 (1942).

[4] Bowden, F. P., Moore, A. J. W., and Tabor, D., *J. Appl. Phys.*, 14, 80 (1943).

[5] Bowden, F. P., and Tabor, D., *J. Appl. Physics*, 14, 141 (1943).

IN the light of Dr. Schnurmann's above remarks, it appears that he is still unconvinced by our original interpretation of frictional data[1] on the Bowden-Leben apparatus, when a small steel spherical surface was slid over copper covered with thin films of soft metals (lead, cadmium and tin), and also by later additional experimental data[2]. It was originally suggested that the reduction in the coefficient of friction, μ, from 0·5 to 0·7 for steel on the bulk metals lead and copper, say, to 0·03–0·08 for films of lead, 10^{-5}–10^{-6} cm. in depth, was due to the combination of a thin soft film on a hard substrate maintaining a small area of contact across which "the adhesion and deformation resistance" was very low. Dr. Schnurmann considers the effect is solely due to a reduction in the "ploughing action".

It would perhaps clarify the argument if an attempt is made to define these terms. The frictional force may be considered to be made up of two contributions[3,4] :

(i) The *adhesion forces* across the real area of contact. This is the shear strength of the metal junctions in Dr. Bowden's recent publications[4,5,7].

(ii) The *deformation forces* required to plough out a groove. This is the ploughing term, the magnitude of which for indium films on steel has been investigated by Bowden, Moore and Tabor[5]. This contribution to the friction may be defined as the force required to deform the metal in the path of the slider, and would contribute to the total friction even if the adhesional forces across the area of contact became zero. The greater drag of a ski on soft snow above that on hard crusted snow is perhaps a simple illustration of a case where the ploughing term is relatively large.

If we consider our original experiments, when a steel ball 2 mm. in diameter was slid over copper and copper covered with a thin film of lead (which recent measurements[6] have shown need only be about 5×10^{-6} cm. in depth for the minimum friction), then since the track width is of the order of 0·02 cm., a simple calculation will show that the area of contact on the bare and lead-covered copper will be practically the same in both cases, since the thin film thickness is only a small fraction of the depth of the sliding groove. This must indicate that the ploughing term is approximately the same in each case. However, since the friction experiments show a tenfold drop in μ to accompany the deposition of this lead film, it must be concluded that *it* is the lower adhesion (or shear strength) between the lead and the steel slider compared with that between copper and steel which is responsible for the drop in μ.

This argument has been put on a quantitative basis in Dr. Bowden's recent publications[4,5,7]. By comparing different forms of slider on soft indium films deposited on hard steel, he has been able to estimate the ploughing and adhesion contributions to the friction for comparatively wide track widths up to 0·2 cm. Thus Fig. 9 of ref. 5 shows that the adhesion term is much greater at low track widths, that is, for the thinnest films such as those used by us. The proportionality between the square of the track width (that is, the area of contact) and the frictional force has been used to show the dependence of the friction on the shear strength across the area of contact, that is, on the adhesion term. It has not been used to support the ploughing hypothesis, as Dr. Schnurmann implies above.

Dr. Schnurmann's analogy of a walking-stick sliding on a gravelled path is perhaps rather ill-chosen on account of complications due to grain rolling; we prefer our original analogy of the lubricating action of lead on a copper substrate being similar to that of a thin film of mud on a smooth road, when the area of contact between a pedestrian or motor vehicle and the road is little different from that on the dry road, while the fall in kinetic friction is a matter of common experience.

Incidentally, Dr. Schnurmann's expectation of a rise in μ followed by a further decrease after breaking through the lead film on copper is at variance with facts. Experiments show the friction to increase from $\mu = 0{\cdot}05$–$0{\cdot}08$ to $\mu =$ greater than 0·3 as the lead film is worn through, until as continued sliding causes copper to pick up, μ may reach a value above unity, and never decreases with further sliding.

If Dr. Schnurmann's results[8] have been incorrectly represented in a previous communication[2], one of us (T. P. H) must plead a misinterpretation of the experimental observations, which on account of their brevity were perhaps somewhat ambiguous. It is, however, difficult to see how the thermo-electric E.M.F. between pairs of sliding surfaces covered with various metal films (each metal having a different thermo-electric E.M.F.) can be considered as a certain measure of the friction μ. No doubt this point will be cleared up when Dr. Schnurmann's detailed results are published at a later date.

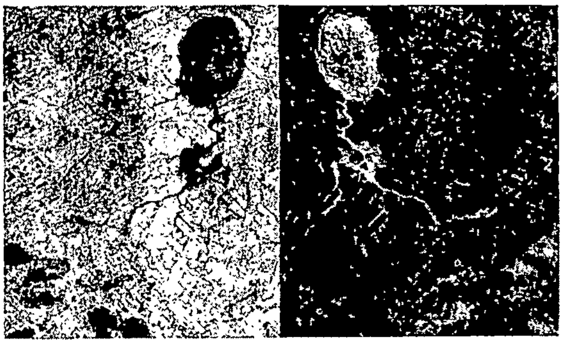
Recording Low Relief in Metallic Surfaces by Cellulose Acetate Moulds

A THIN transparent sheet of cellulose acetate, bearing on one face an accurate mould of the low relief produced in a relatively flat metal surface by abrasion, etching or impact, constitutes a useful permanent record of this relief for comparative purposes. It is superior to a photograph in being three-dimensional, but serves as a negative for photographic copies, if necessary.

Such a mould reproduces both megascopic and microscopic details with exceptional clarity. In particular, it facilitates (*a*) studies of crystalline structures revealed by polished and etched serial sections of ingots, and (*b*) investigation of the changes produced in crystalline structures of polished and etched metallic test specimens by different types of mechanical working.

Recently the method has been utilized for examining polished and etched plane sections of metallic meteorites, iron ores, steels, and brasses. Previously I employed this procedure for investigating the finer structures of rock and mineral surfaces[1]. It is allied to the collodion-mould technique of A. G. Nathorst[2], and the 'peel' technique of J. Walton[3] for studying fossil plants.



POSITIVE PRINT (RIGHT) AND ITS PAPER NEGATIVE DERIVED FROM A CELLULOSE ACETATE MOULD (LEFT) OF THE POLISHED AND ETCHED SURFACE OF A METALLIC METEORITE FROM CAÑON DIABLO, ARIZONA, U.S.A. (HUNTERIAN MUSEUM COLLECT., UNIVERSITY OF GLASGOW).

The mould was 0·08 mm. in thickness and the paper negative made on "Kodaline Slow Paper"; exposure 15 sec. at 30 in. from 100-watt lamp.

A mould is produced from a colourless or dyed dispersion of cellulose acetate in one part by volume of tetrachloroethane and two parts by volume of "Cerric Thinner T. 10" (Cellon, Ltd., Kingston-on-Thames) by (*a*) wetting the cleansed metal surface with some of the dispersing medium; (*b*) levelling and then flowing over this surface a layer of the dispersion, 1–1·5 mm. in depth; (*c*) removing the resulting cellulose acetate film from the surface when volatile parts of the dispersing medium have evaporated; that is, in eight to twelve hours after flowing the layer. Premature stripping of this film from the metal (for example, in four hours) may result in distortion of relief arising from slight shrinkage of the mould parallel to the plane of the metal surface.

This simple process yields strong transparent moulds of refractive index $N_D^{20°}$ 1·49, which are usually between 0·1 mm. and 0·2 mm. in thickness, as much as 1,200 sq. cm. or more in area, light in weight, very flexible, and insoluble in water, cold concentrated hydrofluoric acid, hot Canada balsam and xylol balsam. If such a film is to be kept for reference, its flexibility can be preserved, and ultimate shrinkage reduced, by adding to the dispersion a cellulose acetate plasticizer, such as triphenylphosphate or dimethyl-phthalate, in proportion to the percentage of cellulose acetate present.

The metallic surface is not damaged in any way by the moulding process, but any dust or parts of oxide or other detachable films are removed, and retained by the mould.

For comparison, moulds can be superposed and examined over an illuminated tracing desk. Alternatively, critical parts of them can be cut out and mounted in 'cooked' Canada balsam, for examination under the microscope at any convenient magnification up to about 500 diameters, or by optical projection.

The utility of the method is now being tested in connexion with slags, glasses, ceramic products and refractories.

A Neglected Constituent of Proteins, α-Amino-*n*-butyric Acid

ALTHOUGH its presence in proteins has been reported several times[1–6], α-amino-*n*-butyric acid has not been generally accepted as a naturally occurring amino-acid, probably because no readily reproducible method for its isolation has yet been described. However, the isolation of its hydroxy homologue threonine[7] suggests that α-amino-*n*-butyric acid may occur widely, since whenever a known hydroxy amino-acid occurs in any given protein, the corresponding simple amino-acid is usually present in even larger amounts. Accordingly, it seems probable that an appropriate fractionation of the alanine and valine fractions of a protein rich in threonine would yield appreciable amounts of α-amino-*n*-butyric acid. Hydrolysis should preferably be enzymatic, since prolonged heating with mineral acids has been found to liberate some nitrogen from the synthetic *dl*-α-amino-*n*-butyric acid[8], while *l*-glutamic acid heated with alkalis decomposes to acrylic acid and α-amino-*n*-butyric acid[9], so that misleading results would be obtained by alkaline hydrolysis of proteins. Preliminary work along these lines has been interrupted by the War.

Meanwhile, synthetic *dl*-α-amino-*n*-butyric acid has been increasingly used in comparative studies on amino-acids. No appropriate common name for the amino-acid has yet been proposed. Since the full chemical name is somewhat cumbersome, the term *quadrine* is suggested as a common name. This is intended to call to mind the fact that the acid contains four carbon atoms. α-Amino*iso*butyric acid could be designated as *isoquadrine*.

Cleavability of Keratins Treated with Hot β-Naphthol by Proteinases

WHEN sheep wool is heated with β-naphthol at a temperature of 140–150°, it dissolves; and when after cooling the β-naphthol is removed with ether, an amorphous yellowish substance is obtained in a yield of about 80 per cent of the weight of the wool. This product is readily hydrolysed by a glycerol extract of pancreatin, purified pancreatic proteinase (free of peptidases and protaminase), pepsin, and taka-diastase. Yeast polypeptidase does not affect the product but causes additional hydrolysis after a prior treatment of the product with pepsin.

In a similar manner, chicken feathers were dissolved in hot β-naphthol. The product that remained after removal of the β-naphthol is almost completely soluble in hot 70 per cent alcohol and is precipitated from this solution by an excess of absolute alcohol. The product so obtained is readily cleaved by a glycerol extract of pancreatin, by purified pancreatic proteinase and by pepsin. Like the product obtained from wool, it is resistant to yeast polypeptidase but is cleavable by the latter after a previous exposure to the action of either pepsin or purified pancreatic proteinase.

The products obtained from the two keratins thus behave toward proteolytic enzymes like the 'acropeptides' earlier obtained in a similar manner from other proteins by A. Fodor and collaborators[1].

The experimental part of this investigation was carried out in collaboration with Miss S. Cukerman and Mrs. I. Fodor-Salomonowicz. A detailed report will be published elsewhere.

Vacuum Filtration of Sewage Sludge

VACUUM filtration of sewage sludge, particularly surplus activated sludge from the activated sludge process of sewage treatment, is a well-established process, particularly in the United States, for dewatering sludge prior to drying and incineration or preparation for use as fertilizer or disposal by other means. It has been found from long experience that for successful filtration the sludge must be coagulated beforehand. The coagulant generally used is a ferric salt, usually ferric chloride, and many attempts have been made to reduce the amount of coagulant required with the view of making the process more economical.

Experiments are being conducted on these lines at Manchester Sewage Works, and the finding of other workers[1] has been confirmed that the fresher the sludge the less ferric chloride is required for coagulation. It has also been found that the better the 'condition' of activated sludge from a sewage purification point of view the less ferric chloride is required for coagulation. When activated sludge is kept for periods up to two days, it becomes more alkaline, and this increases the ferric chloride demand. When activated sludge, or a mixture of activated sludge and sedimentation tank sludge, is stored, reducing substances are produced, and these by reducing part of the ferric salt to ferrous salt increase the ferric chloride demand. Aeration of stale activated sludge, or a mixture of activated sludge and sedimentation tank sludge, for a short period (one to two hours) reduces the alkalinity and appreciably reduces the amount of ferric chloride required for coagulation. This may be due in part to oxidation of the reducing substances referred to above. Aeration is beneficial even with the freshest sludge obtainable from the activated sludge plant.

We believe that aeration of sewage sludge, as a preliminary to coagulation and vacuum filtration, has never before been reported. It is hoped shortly to publish the results of the experiments.

INFECTION OF LABORATORY ANIMALS WITH JOHNE'S DISEASE AND LEPROSY

By JOHN FRANCIS

JOHNE'S disease chiefly affects the bovine. It is a chronic bacterial enteritis caused by *Mycobacterium johnei* which produces proliferative changes in, and a rather characteristic thickening of, the intestinal mucosa. The bacteria are usually confined to the intestine and adjacent lymphatic glands. Animals acquire the infection when very young, but the incubation period is protracted, symptoms usually not occurring until two to three years of age or even later; calving or other stresses may cause the onset of symptoms. Clinical recovery may occur, but usually the diarrhœa and emaciation are progressive, eventually resulting in death.

Several workers have remarked on the similarities between the histopathology of Johne's disease and leprosy, and in both the bacteria are largely intracellular. The respective organisms resemble each other in that neither will grow on the usual culture media, and until recently it was generally accepted that laboratory animals had not been infected with *Myco. lepræ*, or with *Myco. johnei*. There was, however, considerable evidence that even naturally susceptible animals became resistant to infection with *Myco. johnei* at an early age, but there was no evidence that young laboratory animals had ever been used in experimental work[1]. I therefore attempted to produce infection by inoculating very young laboratory animals.

Four mice, fourteen days old, were each given intraperitoneally 2·5 mgm. moist bacilli from a culture of *Myco. johnei*. (The organisms were grown on an egg medium containing an extract of *Myco. phlei*. The use of this extract was first described by Twort and Ingram in 1913, see ref. 2.) The animals were re-inoculated with the same dose seven days later. Post-mortem examinations were carried out 9–34 weeks after inoculation, and showed that a progressive infection, commencing in the liver and spleen and eventually involving almost the whole of the intestinal tract, had developed. Seven mice, thirteen days old, received liver tissue from one of these infected mice. The bacilli multiplied in the second group of mice more rapidly than in those originally inoculated. The results of a second mouse passage were largely vitiated due to the early death of the inoculated mice. Another group of thirteen-day-old mice was inoculated with a total dose of 1·4 or 1·25 mgm. of culture from the spleen of an infected mouse. Three of these mice rapidly became heavily infected, but two, killed later, were negative and a third was only lightly infected. Slight infection was also produced in young hamsters, but on the basis of their weights the doses they received were approximately three times smaller than those given to mice. The result was less consistent, but bacilli were carried through one direct animal passage. The cellular reactions in infected mice and hamsters were similar to those in naturally occurring Johne's disease.

Young rabbits and guinea pigs appeared to be less susceptible to Johne's disease than mice or hamsters.

The numerous attempts to infect laboratory animals with *Myco. lepræ* have been reviewed by McKinley[2] and only a few of the more recent need be considered here. Adler[3] splenectomized four 'young' hamsters (*Cricetus auratus*). A fragment of lepra nodule was placed subcutaneously in the operation wound of three of them and in the fourth a fragment was placed in the thigh muscle; material was also inoculated intraperitoneally. One died and no post-mortem examination was performed. The other animals were killed forty days after inoculation. It was claimed that in the remaining two hamsters inoculated subcutaneously local multiplication had occurred and that bacilli were found in the liver. Bacilli were found in the adjacent lymphatic gland of the hamster inoculated in the thigh muscle.

Burnet[4] inoculated six three-month-old hamsters subcutaneously with fragments of leprous tissue. Three of them were splenectomized and three normal. They were inoculated again 15 weeks later and killed 150–220 days after the first inoculation. Only one of the hamsters, which had not been splenectomized, was infected. It had masses of bacilli at the inoculation site and large numbers in the spleen, liver, kidneys, some lymphatic glands and in a testicular abscess. Inoculation of tissue into guinea-pigs showed that this animal was not affected with mammalian tuberculosis.

Burnet and Jadford[5] fed large amounts of leprous skin and spleen to a hamster over a period of twelve days. The hamster died 300 days later after having shown symptoms of malaise. Numerous acid-fast bacilli were found in the spleen and lung, and it was concluded that an active infection had been produced.

De Souza-Araugo[6] inoculated five hamsters (*Cricetus cricetus*) subcutaneously and intraperitoneally with human leprous material; they were given a second subcutaneous inoculation 75 days later. Bacillæmia was demonstrated in three hamsters 163 and 192 days after the first inoculation. Ota and Nitto[7] failed to infect hamster (*Cricetus cricetus*). De Souza-Araugo[6] and Dhamendra and Lowe[8] criticized the validity of Adler's claim to have produced a true infection in hamsters and the latter workers attempted to infect twenty-six adult hamsters, half of which had been splenectomized. Leprous material was inoculated subcutaneously and intraperitoneally but a progressive infection was not produced. Burnet[9] failed to infect hamsters following intra-nasal inoculation.

De Souza-Araugo[10] reported extensive attempts to infect laboratory animals. He claimed[6] that of fifty-nine adult mice, inoculated intraperitoneally with leprous material, 92 per cent developed "systemic infection" (ref. 3). An examination of the results indicates, so far as one can judge, that six or perhaps nine animals developed a true infection. Attempts to infect rats and guinea pigs were less successful.

Jordan[11] inoculated material from typical cases of skin leprosy intradermally into 3–4 month-old white rats. In some of the animals a superficial tumour was produced after 1¼–1½ years. Tissue from these tumours was used for further inoculations. In all, seven passages were carried out in rats and the incubation period was reduced to three–four months, After the first passage, lesions developed in the lung, liver, spleen and kidney; bacilli were not found in the nose. Guinea pigs inoculated with infected material did not become tuberculous. The possibility of the infection being rat leprosy was considered and dismissed: twenty uninoculated rats of the same strain as those used in the experiments died of intercurrent infection, and no acid-fast bacilli were found in their organs. Photomicrographs of lesions in the liver and spleen of infected rats show that the tissue reaction was of the same type as that seen in mice infected with *Myco. johnei*. These are by far the most convincing results so far reported, but they have not been confirmed by other workers and no subsequent paper by Jordan can be traced. Fite[12] inoculated 154 rats, some of which were young, subcutaneously with human leprous material. Six developed a local leprous lesion after an incubation period of 17½–18 months, and in two of them the possibility of a spontaneous rat leprosy infection was as nearly as possible excluded. Material from two rats was inoculated subcutaneously into twelve other rats, ten of which became infected; a second transfer resulted in uniform takes in twelve rats. Unfortunately, the possibility of these rats becoming infected with rat leprosy was not completely excluded. Tisseuil[13] failed to produce progressive infection in rats inoculated subcutaneously with leprous material suspended in various excipients.

Nanoka[14] failed to produce a progressive infection in young chickens inoculated in the breast muscles with leprous material, but Ota and Nitto[7] claim to have carried out six consecutive passages in fowls by mixing the leprous emulsion with Kieselgühr, trypan blue and potassium iodide.

Taken together, the attempts to infect laboratory animals with leprosy are disappointing. Summarizing his results, Burnet[15] states that, of thirty-five hamsters and sixty-three other animals of various species, only two hamsters were infected (these animals have already been described). He concludes that the exact susceptibility of the hamster to *Myco. lepræ* is not yet known, but that it is certainly variable and probably not much greater than that of mice and rats. One feels that the results obtained by De Souza-Araugo[10] in mice and Jordan[11] in rats were quite as promising as those so far obtained with hamsters.

The difficulty of infecting laboratory animals with leprosy is not surprising, because, of some hundred and forty-five experimental attempts to infect man, no fully accepted positive results have been obtained[1]. But leprosy also resembles Johne's disease in that there is a very long incubation period, and children are much more susceptible than adults. The Philippine Islands Leprosy Commission concluded that children are especially susceptible, and that for all practical purposes adults may be considered as immune (Dunham[16]). Rogers and Muir[17] also say that in the control of leprosy "the protection of highly susceptible children is the key to the solution of the problem". They point out that the negative results of the experimental attempts to infect man are of little significance because they were all carried out on adults who had passed the most susceptible age period. They emphasize that in each of four cases of reported infection through vaccination, the patients were children or adolescents of the most highly susceptible age period. They also record two cases in which a child became infected as a result of thrusting a thorn or a needle into himself after it had been removed from the flesh of a leper. "These last two cases have a special significance owing to their having occurred in children of a highly susceptible age, while two such cases can hardly have both been coincidences."

In all the attempts to infect laboratory animals with leprosy, only a few workers have used 'young' animals. There have, however, been no systematic attempts to ascertain the age susceptibility of any species. The similarities between *Myco. johnei* and *Myco. lepræ* and the diseases they produce have been described. In view of the successful results which have been obtained by inoculating very young mice with *Myco. johnei*, it is felt that an attempt to produce *Myco. lepræ* infection by inoculating very young laboratory animals would be fully justified.

Summarizing, neither *Myco. johnei* nor *Myco. lepræ* will grow on ordinary culture media; they also resemble each other in that they are largely intra-cellular parasites and produce the same type of tissue reaction. Adults, even of the naturally susceptible species, are at least partially resistant to Johne's disease and leprosy, and in both there is a long incubation period. Attempts to produce either of these diseases in laboratory animals have not generally been successful. Mice have now been infected with *Myco. johnei* by inoculating them when very young, and it is concluded that an attempt to produce *Myco. lepræ* infection by inoculating very young laboratory animals might meet with success.

EVOLUTION OF THE PLANETARY SYSTEM

WITHIN the last twelve months, a considerable amount of interest has been shown in theories of the origin of the planets and satellites. Two new theories have been advanced, notices of which appeared in NATURE (**150**, 215, and **151**, 200), and now another theory by Lieut.-Colonel K. E. Edgeworth has just been published (*J. Brit. Astro. Assoc.*, **53**, 6; July 1943).

The author starts with a vast cloud of scattered material—gas, dust and small particles with an average diameter of 0·5 cm.—and assumes that this cloud was rotating with angular velocity increasing towards the centre. Owing to inelastic collisions, random velocities were reduced and the rotating cloud became a thin disk in which there occurred an increase in local densities, instability finally taking place. Local condensations, each possessing its own rotation, were formed, but these rotations were slowed down through viscosity, and there was an increase in the central density of each condensation. In many cases these condensations broke up into smaller ones but some coalesced into a number of larger ones by their attraction, and from these larger agglomerations the planets and satellites were formed. The mechanism by which the planets were formed was not necessarily the same as that which was responsible for the formation of the sun, and different suggestions are made regarding this last point, but the author hopes that further investigation will decide which view will be most likely.

The satellites were formed in a similar manner to the planets, the scattered material surrounding the planets forming local condensations which coalesced to form satellites. In the case of the moon and other large satellites, like Titan and Triton, it is suggested that this mechanism was not in operation, and it is thought that the moon was formed of the same primitive material as the earth. The asteroids were formed from condensations which failed to coalesce into larger agglomerations, the perturbations of Jupiter being responsible for this effect. The comets were formed in a cloud of scattered material which may still extend far beyond the orbit of Pluto. Owing to the diffuse condition of the material the condensations did not coalesce, merely condensing on self. While the asteroids developed sufficient cohesion to form solid bodies, the comets remained a mere collection of loose particles. Probably, the great difference of temperature was responsible for this divergence of development.

The theory is stated in a very tentative form and a large amount of detail still remains to be developed. No doubt the author will clarify a number of points which appear to present certain weaknesses in the theory.

THE MUMBWA CAVES, NORTHERN RHODESIA

THE Mumbwa caves have long been known. Yet, in spite of the fact that in South Africa prehistoric cave sites are few and far between, only now has efficient and systematic investigation been undertaken. F. Macrae, many years ago, was the first to make some trial excavations, the resulting finds from which are in the Cambridge Museum of Archæology and Ethnology, but no complete investigation was attempted. Macrae unearthed a really fine Acheulean type of *coup de poing* in the basal level, and this was covered by other layers containing poor Middle Stone Age industries. A characteristic feature was the number of spherical stone balls found. Now at last a detailed account of the whole section actually present has been prepared ("Further Excavations (1939) at the Mumbwa Caves, Northern Rhodesia", by J. Desmond Clark, *Trans. Roy. Soc. of S. Africa*, 29, Pt. III).

At once it must be remarked that the so-called furnace with iron slag said to have been found in the middle levels by a previous investigator (not Macrae) has been shown to have probably been a grave, while the 'slag' has been proved to be merely a brown cave deposit of sand and silt cemented by calcium phosphate and carbonate. Clark found no more lower palæolithic artefacts, and it would seem that the inhabitants of the Mumbwa sites in those times cannot have been numerous. Macrae was evidently lucky. Above the lowest level comes an industry called by Clark the Rhodesian Stillbay, and this in turn is overlain by a Northern Rhodesian Wilton, the whole being capped by a layer containing iron objects. The finds are well illustrated and carefully analysed, and comparisons are made with other discoveries in the region and at the classic sites.

A section on the geology of the caves has been supplied by F. E. Zeuner, and the author has had the advantage of collaborating with I. F. Schofield when describing the Iron Age culture from the uppermost layer. The article as a whole is a very useful piece of work. M. C. BURKITT.

FORTHCOMING EVENTS

Saturday, September 4

BRITISH PSYCHOLOGICAL SOCIETY (at Tavistock House, Tavistock Square, London, W.C.1), at 2 p.m.—"On the Problem of Representative Sampling of the Population".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

TEACHER OF MINING SUBJECTS—The Education Officer, County Hall, Wakefield (September 1).

EDUCATIONAL PSYCHOLOGIST AT THE CHILD GUIDANCE CLINIC—The Chief Education Officer, Education Offices, Northern Secondary School, Mayfield Road, Portsmouth (September 4).

ADVISORY MYCOLOGIST—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (September 4).

LECTURER IN ELECTRICAL ENGINEERING of Degree standard for National Certificate Course, at the South-East London Technical Institute, Lewisham Way, S.E.4—The Education Officer (T. 1), County Hall, Westminster Bridge, London, S.E.1 (September 4).

TEACHER FOR THE CORRECTION OF SPEECH DEFECTS—The Director of Education, Education Offices, Town Hall, Hanley, Stoke-on-Trent (September 11).

HEAD OF THE DEPARTMENT OF MATHEMATICS—The Principal, Heriot Watt College, Edinburgh (September 20).

HEADS OF THE DEPARTMENTS OF PHYSIOLOGY, MEDICINE, AND SURGERY—The Bursar, Royal Veterinary College and Hospital, at The University, Reading (October 1).

CHAIR OF NAVAL ARCHITECTURE—The Acting Secretary of University Court, The University, Glasgow (October 4).

DIRECTOR OF ROBERT GORDON'S TECHNICAL COLLEGE—The Secretary, Robert Gordon's Technical College, Aberdeen (October 16).

LECTURER IN ELECTRICAL ENGINEERING for part-time students taking London University Examinations to Final B.Sc. and Higher National Certificate standards—The Principal and Organizer of Further Education in Rugby, College of Technology and Arts, Eastlands, Rugby.

TEACHERS FOR EVENING CLASSES IN CHEMISTRY up to Intermediate Science standard—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1.

ASSISTANT PORT HEALTH OFFICER for the Basrah Port Directorate, Government of Iraq—The Secretary, Overseas Manpower Committee (Ref. 1034), Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2.

DEPUTY CHIEF CHEMIST—The General Manager, Liverpool Gas Company, Bold Street, Liverpool 1 (endorsed 'Chemist').

SCIENCE AND NATIONALITY

SCIENCE is one of the spheres of human activity which knows nothing of boundaries and frontiers, of races and creeds. It appeals neither to tradition nor sentiment, it has no folk-lore or legends. Its study is free to all, it speaks in one language, it has but one object, but it is the handmaid of all art, all industry and all human progress. "Science, like Nature, to which it belongs," said Davy, "is neither limited by time or space. It belongs to the world and is of no country and no age." Pasteur's view was that "Science has no nationality because knowledge is the patrimony of humanity, the torch which gives light to the world". It is justifiable to write of Chinese art, Byzantine art, Moorish architecture, Italian painting, Greek sculpture and Russian literature, but science cannot be divided into such chapters. The contributions of the ancient, the medieval and modern worlds and of all continents are interwoven and inseparable. Illimitable in its extent, the edifice of science may be compared with the temple of art of which Lafcadio Hearn wrote to the musician Krehbiel. In this temple, he said, "the more you advance the more seemingly infinite becomes the vastness of the place, the more interminable its vistas of arches and the more mysterious its endless succession of aisles. . . . The Vatican with its sixty thousand rooms is but a child's toy house compared with one of the countless wings of art's infinite temples." In the erection of this great structure of science, a multitude from many lands have assisted, and their work is seen to-day in the sky and on the sea, in factory and field and around our hearths and homes, touching every side of life.

But though science knows nothing of frontiers and boundaries, its investigators have homes and belong to some particular community, and it is but natural that these communities should take a special pride in their notable men, upholding their reputation and honouring their memory. Thus it comes that memorials are set up where the great were born, where they laboured and where they died, and such memorials become the shrines around which on appropriate occasions commemorations are held.

The question of what it is that moves all mankind to commemorate its great men was asked and answered by the late Prof. Wilfred Trotter in his Hunterian Oration to the Royal College of Surgeons of England on February 15, 1932. "The *conscious* and *ostensible* motives," he said, "under whose influence we approach the commemoration of great men are first, to contemplate in humble piety and emulation a largeness of mind and character that far exceeds our own, and secondly to seek inspiration from struggles heroically engaged and perhaps triumphantly won." Elsewhere it was written: "we commemorate to instruct ourselves, to inspire others to act in a way similar to that of the men we revere, perhaps most of all to impress the fact of the debt of the living to the past". In the first of his seven essays on "Representative Men", Emerson remarked, "The knowledge that in the city is a man who invented the railroad raises the credit of all the citizens". As with a city so with a nation, and one cannot but feel his own status raised by the knowledge that the great men of the present or the past belong to his own community, and all gain something from association with historic places connected with notable events or outstanding men. We all have our heroes, from whom we gain vigour and resolution, for as Carlyle said, they are "profitable company". If the hero is a Pasteur so much the better, for he it was who advised the students of Edinburgh "to associate the cult of great men and great things with every thought". It is given to but a few to come into intimate contact with the really great, but no student of science need lack knowledge of the lives and characters of famous men of science, for biographies and histories abound. It may be, as Prof. Trotter said, that "in all our commemorations, whether by word or plastic act, we make our own pictures and drift increasingly away from the actual man"; but pictures we must have, and our debt is great when a biographer succeeds in delineating vividly the man of whom he writes. "In the written records of the lives of men and women," said Lord Oxford, "we have all a common territory, inexhaustible in its range, permanent in its interest, from which pedantry itself cannot shut us out."

Inspiring and valuable as the biographies of men of science may be, still more important are the histories of science which, when written in an impartial spirit by men of knowledge and experience, provide those broad and unbiased views which are the birthright of every student. Men of science have come from all classes and all lands, a Siberian town giving birth to a Mendeléeff, a Serbian village to a Tesla and an Indian home to a Ramanujan. When von Zittel was asked to write his history of geology, it was suggested that he should record chiefly the progress of that science in Germany, but he was unwilling to accept any such limits. "All civilized nations," he wrote, "have shared in the development of the natural sciences, the history of any one of which is to a certain extent the history of a scientific freemasonry." His countryman, Prof. Matschoss, of whose death we regret to learn, in the preface to his excellent book "Great Engineers" took much the same view, remarking that "Technology is not confined within frontiers, and there is nothing in it that anyone can do entirely alone. The threads run from nation to nation and from generation to generation."

The records of all important scientific societies give evidence of the international character of science, and it is one of their self-imposed tasks to recognize outstanding achievements in lands beyond their own. The lists of the foreign associates of the Paris Academy of Sciences, the roll of the Copley medallists of the Royal Society, and the table of the Nobel laureates all illustrate the scientific freemasonry of von Zittel. Unfortunately, war between nations always brings in its train boasting and jealousy, gravely injuring the feeling of brotherhood, but in the end histories of science have little to say about dictators or tyrants, conquests or defeats. When the present disastrous struggle ends, it will be the privilege of men of science to attempt to allay national animosities and to resume speedily the friendly relations of happier times. It is much to be hoped that the day will soon come when it will again be possible to hold international gatherings, and to propose toasts similar to those given at the meeting of the American Institute of Electrical Engineers in 1901. On that occasion homage was paid to science in France, England, Germany, Italy and the United States by the toasts: "The land of Ampère; the country of Faraday; the successors of Ohm; the heirs of Volta and the legatees of Franklin".

Though the question of nationality cannot be said to be of capital importance, yet there is an urge to delve into the ancestry and early environment of notable men, and to attempt to trace the things which have influenced their careers. Nationality, of course, may be inherited or acquired. Usually the place of birth and ancestry conspire together to determine nationality, but sometimes place of birth has little to do with it. Cavendish was born at Nice, Black at Bordeaux, Lagrange at Turin, and Regnault at Aix la Chapelle, but everyone knows the first two were British and the other two French. All the early American men of science such as the Winthrops, Cotton Mather, Rittenhouse and Franklin were originally British subjects. Since, through the Revolution, Rittenhouse and Franklin became citizens of the United States, there has been a constant flow of men from many European countries across the Atlantic who have willingly abandoned their old nationality for a new. Graham Bell was born in Scotland, Elihu Thomson in England, Michelson and Berliner in Germany, Agassiz in Switzerland.

In most cases, there is no doubt about a man's nationality, but as has recently been seen in the discussion about Copernicus, the matter is sometimes complicated by various circumstances. On the occasion of the quatercentenary of Copernicus *The Times* wrote: "The middle of a great war between Poland and Germany is not perhaps the most suitable occasion for reviving an ancient controversy as to his nationality", and though Copernicus was born at Thorn, "the troubled history of that corner of Europe makes it difficult to speak with any certainty about his ancestry". There are many other corners of Europe with troubled histories—Alsace, Finland, Schleswig-Holstein and the various countries which made up the old Austro-Hungarian Empire. Many men have been good Austrians without a drop of Austrian blood in their veins. The great geologist Eduard Suess (1831–1914) was the son of a German merchant and was born in London. For nearly seventy years he lived in Vienna; but he retained his affection for England, which he called his 'native land'. When in 1929 a tablet was unveiled on No. 4, Duncan Terrace, Islington, London, his birthplace, Prof. J. W. Gregory said that "he made the higher study of geology international and thereby encouraged the growth of the international spirit". Another name famous in Austrian scientific circles was Littrow. Joseph Johann Littrow (1787–1840) and his son Karl

Ludwig Littrow (1811–77) were both directors of the Vienna Observatory. The elder of the two was born and educated in Bohemia, and in 1810 went to Kasan, Russia, where the younger was born. The famous naturalist Johann Gregor Mendel (1822–84) was always an Austrian subject, but his birthplace was the Silesian village of Heinzendorf, and his work on heredity was done at the old monastery at Brünn, Moravia. Ignaz von Born (1742–91), who was in the first rank of European mineralogists, and a councillor of state at Vienna, was a native of Carlsburg, Transylvania, now a part of Rumania.

That troubled corner of Europe, Alsace, now again in German occupation, belonged to France for nearly two centuries before it was annexed by Germany in 1871, only to become French again after the War of 1914–18. It has given a long line of distinguished men to France. Strasbourg was the birthplace of the chemists Wurtz, Schutzenberger, Friedel and Gerhardt. Pasteur once held a chair in its University and his statue was erected there. Other men of science have come from Colmar and Mulhouse, nearly all of them of French nationality. Another 'corner' of Europe—Holstein—was the birthplace of the astronomer, F. G. W. Struve (1793–1864). The Struve family is sometimes spoken of as German, but the astronomer was the son of a Danish schoolmaster and was born at Altona, a city which had been Danish for a century and a half. By their work at Dorpat and Pulkova, Struve and his son became subjects of the Russian Tsars and also great international figures.

Of all countries, with the exception of the United States, none has benefited more by the labours of men of science of foreign birth than Great Britain. To-day, history is only repeating itself, for our love of liberty and our free institutions have again and again made our land a sanctuary for men fleeing from religious or political persecution. When Louis XIV, by the Revocation of the Edict of Nantes in 1685, drove half a million of his most industrious subjects to seek asylum abroad, many of them came to England. To this we owe the Dollond, Demainbray and Desagulier families, all known in the history of science—the Dollonds for their optical work, the Demainbrays for their labours as the King's astronomers at Kew, and the Desaguliers, father and son, for their respective studies in natural philosophy and gunnery. With the Dollonds also came Abraham Demoivre, the mathematician and close friend of Newton. The accession of George I naturally led to closer relations between England and the Continent, and from Germany to Great Britain came Dillenius, the professor of botany at Oxford, John Müller, the first headmaster of the Royal Military Academy, Woolwich, and the most famous of all British astronomers, William Herschel. From Sweden came Solander, keeper of natural history in the British Museum ; from Italy, Cavallo, the electrician ; from Holland, Ingenhousz, physician and physicist ; and from Switzerland, Dr. Marcet, whose wife, Mrs. Marcet, a Swiss woman wrote the book on chemistry which stimulated Faraday. Another native of Geneva resident in England was Deluc, the geologist and meteorologist, and it may be recalled that W. T. Brande, the colleague of Faraday at the Royal Institution, was the son of a Hanoverian medical man. There are many other names inscribed in the history of science in Britain, like those of Rücker, Meldola, Sabine, Kater, Negretti and Siemens, which remind us of our debt to other nations.

Another chapter in the relations of Great Britain with Germany opened with the marriage of Queen Victoria and Prince Albert. It was largely due to the Prince and Sir James Clark, the Court physician, that the Royal College of Chemistry was opened in 1845 with Hofmann at its head. Three years previously, Liebig, accompanied by Dean Buckland and Lyon Playfair, had made a sort of triumphal tour through England. Playfair had studied under Liebig at Giessen and from that time onwards British students of science flocked to Giessen, to Göttingen, to Heidelberg and so on, to sit at the feet of Wöhler, Bunsen, Kirchhoff and other famous teachers. Tyndall, Frankland, Muspratt, Gilbert, Williamson, Gladstone, Sylvanus Thompson, Perkin, Smithells, Roscoe and Ramsay are a few of the distinguished men who worked in German laboratories. From Germany, too, came Voelcker, Dupré, Sprengel, Hugo Müller, Ludwig Mond, Messel, Dittmar, Schorlemmer and many besides to teach or engage in industry in Great Britain. The remarkable comradeship which existed between Continental and British chemists in the time of Victoria is fully shown in the series of memorial lectures delivered to the Chemical Society.

Though there is no question that Great Britain, and the British Empire also, have benefited greatly by the labours of men of foreign nationality, the debt has been by no means one-sided. As British chemistry students went to Germany, so foreign students came to England to learn engineering and shipbuilding. Mechanical engineering in Sweden, Russia, Italy and Switzerland owes much to such as Owen, Baird, Guppy and Charles Brown. It was William Wilkinson who erected the first blast furnaces at Le Creusot, and from the original works of Philip Taylor sprang the Forges et Chantiers de la Méditerranée near Toulon. One of the makers of modern Hamburg was the civil engineer William Lindley, whose son, Sir W. H. Lindley designed public works for Frankfort, Budapest, Baku and other places. At one time there was a British engineer in every port in the world from Tokyo to Buenos Aires.

All these facts go to show that there can be no such thing as isolation in scientific matters. In March 1942 Sir Henry Dale, in a letter to *The Times* about the tercentenary of Newton, said that his achievement in science is the heritage of all men. This applies equally to every scientific inquirer, from the most brilliant genius to the humblest of those who endeavour to increase natural knowledge ; and in honouring such men as Kepler, Galileo, Harvey, Swammerdam, Berzelius, Newcomb, Fresnel, or Pavlov, we pay homage to the great band of seekers after truth wherever they were born or whatever their nationality.

PROLEGOMENA TO PLANNING

Creative Demobilisation

(International Library of Sociology and Social Reconstruction.) Vol. 1: Principles of National Planning. By E. A. Gutkind. Pp. xvi+331. 21*s.* net. Vol. 2: Case Studies in National Planning. Edited by E. A. Gutkind. Pp. viii+280. 21*s.* net. (London: Kegan Paul and Co., Ltd., 1943.)

ALLIED successes in the autumn of 1942 were immediately reflected in Great Britain in the new focus of attention towards post-war programmes and policies. The warm welcome of the Beveridge Report was in large measure attributable to its timely appearance. Since then dozens of plans for agriculture, for particular industries, for special areas and for bombed cities have appeared. Yet it is remarkable that there have appeared only two works which discuss comprehensively the objectives and principles of planning. Prof. Hutt diagnoses pre-war trends and practices in his "Plan for Reconstruction" and outlines a consistent post-war economic policy for Britain which, he believes, removes the major defects that have hitherto marred a smooth working of economic forces. The second work is that by Dr. Gutkind, who establishes the general principles of town and country planning, and applies them to Britain. It would be instructive to examine the common features of these two essays, both of which are published in the International Library of Sociology and Social Reconstruction. Here, however, we can simply note the sense of urgency with which both authors write. Dr. Gutkind believes that "failure to identify the demobilisation with a creative beginning of a new era will be tantamount to a new declaration of war". The unpreparedness for peace shocks him, yet he will have none of hand-to-mouth policies. From the armistice we must concentrate our whole might on the "goal of making Britain one good house"; and this attitude helps to explain the author's impatience with possible criticisms of his approach, and his contempt for *laisser faire.*

The first volume, of which Dr. Gutkind is author (of the second he is editor), states that the foremost objective of town and country planning is the creation of an inspiring and diversified environment. With this few reasonable men will quarrel, but that general agreement is likely to evaporate when the general principles the author formulates come to be applied. The chief of these principles is the decentralization and dispersal of settlement. We are told "Decentralisation should be understood not in the narrower sense of decentralisation of industry but in its broader meaning of decentralisation of settlement—the loosening up of too densely populated urban districts by the development of new, or by the further development of existing, places within the direct sphere of influence of the urban centre which is to be re-developed. Dispersal, on the other hand, can be defined as the same process but spreading beyond the confines of the area from which the overflow is to be drained" (p. 219). The fundamental aim of pursuing a national plan which embodies these principles is the fashioning of the environment of man according to his social needs as a free individual. This involves the establishment of a sound balance between the four functions—housing, working, distributing and recreating—which constitute our being. This functional division is analogous to the division, made by the classical economists, of the productive process into production, exchange, distribution and consumption, and the use of this analogy might have facilitated the exposition of the idea of a 'balance'. The notion of a balance of these functions is Dr. Gutkind's yardstick, which is applied in successive chapters to British agriculture and industry.

In Great Britain to-day more muddled thinking is devoted to the ills and future of agriculture than to any other topic, with the possible exception of finance. What happens when Dr. Gutkind applies his principles? They lead him to identify himself wholeheartedly with the school of thought which has found its most recent expression in the majority report of the Scott Committee on Land Utilisation in Rural Areas. "Agriculture", says the writer (p. 123), "must be accepted as a basic industry, and its fundamental function in the national economy must govern its development—neither charity nor antiquarian æsthetics are a sufficient basis for an agrarian policy." But what is the sufficient basis?

Although the nineteenth century belief in cheap food might have gone too far and suffered from a measure of shortsightedness, it was not without some solid justification both from the national and international points of view. Freedom from want cannot be comfortably maintained if every national area adopts autarchic agrarian policies on social grounds. The legacy of fear and distrust left by the War of 1914–18 and the Great Depression will not be thrown off, much less the fuller life be attained, by such policies. The limits of Britain's ability in this direction without multiplying costs many-fold have been revealed in two major wars. Similarly, in respect of industry Dr. Gutkind's criticisms of past trends are somewhat immoderate. In spite of the tendency of socialist thought in Britain and industrial methods in the U.S.S.R., Dr. Gutkind maintains (p. 209) that "A further argument in favour of decentralised and scientifically run industrial units is the reduction of competitive conditions; that is important as it tends to eliminate the race for 'a place in the sun', that is, it reduces the agglomeration of industry within one region which might, as it actually has done, offer some alleged advantages over competitors who remain outside this particular region". Would he countenance pseudo-competition?

With the aid of diagrams a plan for the physical transformation of town and country is unfolded. Here the author's views agree with those of Lewis Mumford. Three stages of action are suggested in order to accomplish the functional plan: first, the splitting up of the whole congested area into sections by a system of linear arteries, thus producing the primary grid of green belts and roads which permits of recreating and distributing; secondly, the differentiation of these sections among the main categories of use by a system of spatial zoning which creates an organism of residential and non-residential districts for housing and working; and, thirdly, the further subdivision of these units by a system of 'functional spotting' which leads to a secondary grid of open spaces and streets. In this way a functional balance is gained. The scheme is ably evolved.

In the second volume the twenty-two separate memoranda are grouped similarly to the main chapters of Vol. 1. Profs. A. W. Ashby, J. H. Jones and A. G. Ogilvie, and Messrs. E. G. Bowen and J. R. Currie are among the contributors. All future workers in this field will be grateful to Dr. Gutkind for bringing together such an array of facts and views as we find here; and there is a need for further work. Dr. Gutkind has not said the last word on the principles of national planning. He has made a useful, provocative beginning, and not sought finality.

D. J. MORGAN.

HOMES AND INCOME

(1) An Enquiry into People's Homes

A Report prepared by Mass-Observation for the Advertising Service Guild. ("Change" Wartime Surveys, No. 4.) Pp. xxiv+228. (London: John Murray, 1943.) 10*s*.

(2) War-time Pattern of Saving and Spending

By Charles Madge. (National Institute of Economic and Social Research, Occasional Papers, 4.) Pp. viii+140. (Cambridge: At the University Press, 1943.) 6*s*. net.

(1) ALL but the least observant would agree that the war motive that governs the actions of the people of Great Britain is not only to defeat the common enemy but also to create by exertion and example a nobler Britain and a happier world. This report has been prepared by Mass Observation for the Advertising Service Guild as a contribution to the responsible task of rebuilding a better Britain; with its publication these two bodies have earned the gratitude of every man of goodwill.

The merit of this inquiry into housing conditions and services is that it was undertaken at the level with which post-war planners will have to deal if they are to see their schemes go beyond the paper stage—the level of the people. To-day we are assailed by the conviction that this is to be the age of the common man. It is fitting, therefore, that inquiry should be made into the way the common man lives and the way he would like to live. If he can see that reconstruction involves accomplishment of some of his dreams and desires, the more likely is the British citizen to continue his labours unabated during the immediate post-war period, with all its reaction from stress and strain, and build up a better ordered society.

The survey was chiefly concerned with attitudes to housing among the working classes and was carried out in eleven different places in England, starting in August 1941 and finishing in April 1942. These places were chosen to cover representative types of housing: old houses, L.C.C. estates, garden cities and flats—and, where possible, districts were selected where another social survey had been conducted by Mass Observation before the War, so that comparative pre-war data should be available. In 90 per cent of the cases the people interviewed were housewives; whether this was expedient or from choice the report does not make clear. Important age and sex differences between those interviewed are carefully analysed, while the entire sample was almost evenly divided between the two working-class grades, skilled workers or artisans, and unskilled workers. The results of the survey are comprehensively recorded and will amply repay close study by architects, sociologists, politicians, town-planners, civil servants, etc.
